Network Archaeology delivers a complete consultancy and field service nationwide. The company's particular expertise is linear infrastructure, such as pipelines, roads, rail and cables. Its emphasis is upon good communication and recognition of clients' individual needs and priorities. Network is known for delivering professional support, taking care of the archaeology and enabling projects to keep moving forward.

1 Summary

An archaeological scheme of work, including strip, map and record, a watching brief and limited excavation was undertaken by Network Archaeology during upgrading and replacement of the electricity network between Spennymoor in County Durham and Norton in Teesside.

Two small, Romano-British rural farmsteads were revealed at Butterwick Road (Access 27) near Fishburn in southern County Durham, and at Low Middlewood (Access 37) near Thorpe Thewles on Teesside. A single, heavily truncated, Roman pit was also recorded at East Close (Access 35) near Thorpe Larches on Teesside.

Later remains were restricted to remnants of medieval ridge and furrow agriculture, particularly noticeable near the deserted and shrunken medieval settlements along the route such as near Layton on Teesside.

It is noticeable that stretches of the route appear to be devoid of both archaeological features and metal detected finds, particularly between Coxhoe and Trimdon where the route crosses open farmland. This may suggest that parts of the landscape have remained relatively uninhabited and under utilised away from existing settlements and the known abandoned or shrunken medieval communities.

Systematic metal-detecting recovered a moderate collection of metalwork, strongly biased towards agricultural and domestic 19th and 20th century objects. However, several notable finds included a 16th century silver hairpin at Cornforth Lane (Access 13) in County Durham, a 4th century Roman coin from Trimdon (Access 22) in County Durham, an Edward I silver penny at Carlton (Access 40) on Teesside, and a medieval lead spindle whorl at Norton (Access 41) on Teesside.

2 Introduction

2.1 Scheme background

2.1.1 Reasons for development

The aim of the development was to upgrade and replace a section of the national electricity transmission network. This replacement system will be able to transmit increased amounts of electricity from newly built installations, which harness renewable energy sources in northern England and Scotland. The pre-existing network, constructed in 1975, had the capacity to transmit 275kV of electricity, while the replacement system will be able to relay almost double the capacity of its predecessor (Environmental Statement Volume 1, National Grid 2009).

2.1.2 Scheme details

A total of 69 replacement towers, which facilitated the new network, were constructed between the Spennymoor Substation in County Durham and the Norton Substation in Teesside. The route of the replacement tower scheme, namely the ZXC overhead line, was dictated by the route of the earlier XC overhead line scheme. In some instances the routes converged and some ZXC towers were constructed directly in place of the dismantled XC towers. Two short sections of the 4TF route were also constructed as part of the scheme. The 4TF system was required to swap circuits from the XC route to the ZXC route.

The development primarily required access to plots of land which contained the XC overhead line network for a programme of tower dismantlement, as well as access to the proposed site of the ZXC towers. To assist in accessing the fields whilst minimising the burden of the construction traffic, a series of temporary access tracks, 4m wide, totalling an approximate length of 20km, were constructed.

In most cases construction of each access track entailed the removal of the topsoil to an approximate depth of 0.3m with a mechanical 360 excavator. A thin membrane of a geo-composite membrane (Tensar's TriAx T160-G) was cut to the correct width and placed within the access track which then received an appropriate amount of crushed aggregate up to ground level. Once the access tracks were connected with the proposed tower site, a square working area and crane pad was instated around the footprint of the tower.

The entrances to the overhead line tower accesses were mostly located at intermittent points off category A or B roads. Funnel shaped 'bell-mouths' were built at the entrances to assist in safe access and egress to the site. The bell mouths were constructed using the same methodology as the access tracks.

The foundations for the towers consisted of four square pits distributed in a square formation. Each foundation pit was 4m deep and between 3.6m and 5.8m square dependant on the size of the tower.

On smaller plots of land which were expected to receive smaller amounts of construction traffic, a series of steel plates were positioned on the ground to reduce the amount of ground works within the field. Once the overhead line was in operation, all of the temporary access installations were removed and the fields were re-instated.

2.1.3 Project commission

Network Archaeology was commissioned by MWH (UK Ltd) to undertake all required archaeological fieldwork and reporting relating to the project. Network worked alongside the Electricity Alliance East who controlled the project on behalf of National Grid.

The Electricity Alliance East employed Balfour Beatty Civil Engineers Limited (BBCEL) to undertake work on all access tracks, bell-mouths, tower working areas, steel track installation and crane pads along with smaller sundry works. The tower foundations, tower erection and dismantlement teams were from Balfour Beatty Utility Solutions Limited (BBUSL).

2.1.4 Route (Figs 1-4)

The 21.5km long ZXC overhead line route progresses directly east from the Spennymoor Substation, (NGR 428900 534200), sited 3km east-north-east of the centre of the town of Spennymoor. The route proceeds east and crosses the route of the East Coast Main Line railway and continues in a straight line north of Cornforth where it crosses the A1. The easterly alignment changes at this point to an east-southeast alignment which continues towards Trimdon. At Trimdon, the route sharply turns to the south-south-east in the direction of Fishburn. The route turns south where it runs parallel to the town of Sedgefield and crosses the A689 where it gradually bends to the south-east. This section of the overhead line progresses to the east of the A177 and continues in broad alignment with the road for roughly 5km. Approximately half way along this stretch of the overhead line, at Thorpe Larches, the route passes from County Durham into Teesside. The route finally turns south where it crosses the A177 and terminates at the Norton Substation (NGR 441100 522000).

2.15 Construction

The principal construction activities requiring archaeological investigation were:

- Soil stripping of new access tracks to new towers and the creation of associated bell-mouths at roads;
- Soil stripping of working areas around 69 new towers, and
- Excavation of tower foundation pad pits.

Access to the towers was via a combination of existing tracks (which did not require stripping) supplemented by a series of new tracks which were stripped under archaeological monitoring.

2.16 Construction programme

Construction was programmed to start the week commencing 4th January 2010, taking a period of approximately 29 months to complete. Archaeological field work began on the 4th January 2010 and was concluded by the 30th of September 2011.

2.17 Legislation, regulations and guidance

National Grid submitted an application to the Department of Energy and Climate Change (DECC) on 3rd July 2009 for consent, under Section 37 of the Electricity Act 1989, for the installation of above ground of electricity lines and for a direction that planning permission be deemed to be granted. The application was supported by an Environmental Statement, Planning Statement and Consent Application Drawings.

DECC granted consent to National Grid on 10th Dec 2009, subject to a pre-commencement condition relating to archaeology: Condition 3: 'No development shall take place until a programme of archaeological work in accordance with a mitigation strategy as set out in the attached conditions provided by Durham County Council has been submitted and approved by Durham County Council. Reason: To protect areas of archaeological interest. Durham County Council's Form B records a series of 'suggested conditions'.

These Conditions were addressed by an archaeological Specification and a Written Scheme of Investigation (Network Archaeology 2010).

2.2 Geology and topography of the route (Fig 5)

The route of the overhead line replacement scheme can be partitioned into three distinct geological zones. The north-westernmost of these, on the largely undulating ground between the 110m and the 80m AOD contour, is the Pennine Middle Coal Measure (BGS 2012). The bedrock of this part of the Coal Measure can be characterised as sandstone and mudstone, mixed with occasional beds of siltstone. It extends from Spennymoor until the northern peripheries of Cornforth. The superficial geology is Devensian diamicton till and remains so until Fishburn and Sedgefield.

In contrast, the magnesian limestone hills towards the east, on which the villages of Trimdon and Fishburn are located, has fewer dramatic undulations and reaches up to 120m AOD. Both the Raisby and Ford dolostone formations account for the dominant bedrock of the limestone hills. The superficial geology becomes far more variable and includes alluvial clays, sands, silts and gravels. This mixed and variable geology continues south until Stockton on Tees.

At the river Skerne, approximately 100m AOD, the bedrock changes to the Roxby formation of calcareous mudstone. Within the Skerne valley there are other stratified bedrock deposits such as Seaham limestone and Edlington calcareous mudstone. The relief gradually becomes gentler with fewer severe hills and a more rolling landscape. The bedrock continues to be the Roxby formation and the height decreases to 40m AOD at Thorpe Thewles towards the Tees Valley.

2.3 Modern landuse (Figs 1-4, 6)

The north-west section of the route avoids major settlements and passes through farmland comprising mixed managed pasture and arable crop with little or no woodland. The seasonally wet acid and clay loams found near Spennymoor allow some arable cultivation, though are historically more suited to grazing and woodland. The route then passes through cultivated lime-rich loams on the edge of the limestone escarpment and the adjacent slightly acid loams before passing to the north of a pocket of Carr and fenland formed from glacial meltwater. Finally, the route crosses a large expanse of seasonally wet clay loam which stretches to the edge of Norton and is utilised as mixed pasture and managed grassland.

The landscape immediately northwest of the route, lies over rich coal measures, and has been historically mined for coal and other minerals, though most of the mines and quarries are now abandoned.

3 Previous Archaeological Work

3.1 Previous work

Preliminary work conducted prior to fieldwork included a Desk Based Assessment (Cultural Heritage Chapter 10) and a walkover survey. The assessment was required to consider the cultural heritage resources including Listed Buildings, Scheduled Monuments, Conservation Areas, Registered Parks and Gardens, Battlefields and palaeoenvironmental deposits within a 2km radius of the existing XC route. Information pertaining to these cultural heritage assets was obtained from various government departments and institutions including English Heritage, Durham University Library Archives and Special Collections, cartographic sources, and Tees Archaeology Historic Environment Record. The significance of the cultural resource was assessed as well as the potential impact imposed by the development.

Potential resources identified included stray finds of un-stratified prehistoric artefacts and the cropmarks of several possible Bronze Age ring ditches present within the route corridor. A number of enclosure sites of possible Iron Age/Romano-British date have also been recorded. The ZXC overhead line crosses the line of Cade's Roman Road to the east of Cornforth, though there are no other recorded Roman period sites along the development route. Unstratified Roman finds have been recorded southwest of Metal Bridge, west of Wynyard Park and to the south-west of the Norton Substation. There was no substantial archaeological evidence for settlement or activity dating to the early medieval period within the study area. Whilst the potential for unrecorded settlement of medieval date was also considered to be low, evidence of the former medieval agricultural landscape is widespread, primarily in the form of field system complexes of ridge and furrow cultivation. This has mainly been recorded from aerial photographs and the majority has been ploughed-down with little surviving as upstanding earthworks. A range of post-medieval industrial features, comprising former railways, coal mining remains and quarries of various types are recorded within the route corridor both as extant features and from documentary/cartographic sources.

3.2 Research aims

Research aims have been drafted in consultation with The North-East Regional Research Framework for the Historic Environment (Petts, D and Gerrard, C 2006), Tees Archaeology, and Durham County Council.

- The metal detecting survey across the entire route of the development is an unprecedented venture for a developer-funded project in the region. The survey should characterise the quantity and type of metal artefacts likely to be discovered in this part of north-east England.
- Mesolithic flints are found in large concentrations between the Tyne and the Tees. This has led some (Harding 1995) to suggest that there were significant Mesolithic migratory routes from east to west. Casual flint finds discovered during the monitoring may allude to more defined routes.
- The project has an opportunity to assist with the understanding of Iron Age and Romano-British settlements on the Magnesian Limestone escarpment and the upland fringe of the Coal Measures. Chronologies and morphologies of settlements from these two periods are poorly understood, especially on the lowlands.
- Understanding the impact of Roman control in the North-East of England varies greatly across the region. Little is known about the impact of Roman frontier expansion between the Tyne and the Tees and to the west of the Stainmore and Lanchester forts. Any Roman remains encountered during the project may assist in understanding this topic.
- Parts of the development pass very close to 'Cades' Roman road. This presents an opportunity whereby finds or features associated with the construction of the road

may be encountered. The date and chronologies of surrounding contemporary settlements such as West House enclosed settlement and Garmondsway may therefore be better understood (Clark, P.A.G and Gosling, P.F 1976/Proctor, J 2009).

- The noticeable absence of Early Medieval settlements within close proximity of the development will be further investigated. There is a genuine opportunity to understand more about the apparent abandonment of the lowlands or alternatively investigate if the absence is a condition of archaeological preservation.
- Ridge and Furrow is likely to be a common feature during the programme of archaeological works. Certain aspects of later medieval agricultural development, such as the formation of ridge and furrow, are still uncertain. A more focused investigation may provide evidence for such developments.
- Certain parts of rural County Durham are known to have had dramatic fluctuations in population during the 14th century. This is believed to have been as a result of the Black Death, as well as several other plagues, soil exhaustion and crop failures. Any noticeable prolonged absences in this period may be identifiable in the archaeological record.
- The development of major industrial intensifications began in the 16th and 17th centuries. The genesis and development of industry may be understood more in the Tyne Tees corridor as a result of this programme of works.

The significant scale of the development has the potential to increase our understanding of the effects which modern industry and land use have had on archaeological remains.

3.3 Potential impacts

The WSI noted known archaeology at risk during construction; this is detailed in Table 3.1 below, with the site name given during post-excavation added for clarity:

Tower	Site Name	Known Archaeology	Date
9	Grindon	Field system	Medieval
12	Grindon	Flint findspot	Prehistoric
27	Butterwick Road	Unclassified earthwork	unknown
49-50	Stobb Cross Lane	Roman Road	Roman
51	Stobb Cross Lane	Railway	Modern
52	Cornforth Lane	Mill	Postmed/Modern
54	Cornforth	Circular cropmark	unknown
12.1	Grindon	Limekiln and quarry	Postmed/Modern

Table 3.1 Potential Impacts

4 Scope of Works

4.1 Objectives

The general objectives detailed in the WSI are as follows:

- · To identify, appropriately manage and fully mitigate the archaeological resource affected by the proposed development;

- · To consider, in all cases of archaeological discovery, whether preservation *in situ* is desirable and achievable as the foremost response;
- · To determine, where preservation *in situ* is not desirable or achievable, an appropriate strategy for preservation by record;
- · To develop, where possible, knowledge and understanding of the historic landscape and archaeological resource through recording of threatened remains;
- · To determine and understand the nature, function and character of any archaeological remains in their cultural and environmental setting;
- · To obtain a chronological sequence for the human activity and to place it within its regional context;
- · To establish the ecofactual and environmental sequence and context of archaeological deposits and features;
- · To engage in a programme of post-excavation, archiving, synthesis and study, leading to publication and dissemination of results, and
- · To ensure the long-term survival of the information through deposition of a project archive and any reports generated at the County Durham and Tees Archaeology Historic Environment Records and the National Monuments

4.2 Strip map and record

The monitoring archaeologist supervised the machine excavation of a controlled strip of the soils to reveal the natural drift geology and any archaeological features.

Each tower was recorded with a pro-forma specifically designed for the project. The pro-forma recorded the geographic position of each of the four foundations along with a representative section of the stratigraphy of one of the foundations. Context numbers were allocated where appropriate. A suite of photographs were taken of the foundations regardless of the presence or absence of archaeology.

The context numbers allocated to the monitoring and excavation of the tower foundations are five digits long. The tower number is indicated by the first two numbers whilst the following three numbers relate to the context, such as 221001

Tower bases were routinely visited at various stages to maintain a record of the natural drift geology.

4.3 Watching brief

A programme of archaeological monitoring in the form of a watching brief was conducted on all access tracks and sundry works under the code SPN16.

The watching brief comprised permanent presence supervision by an archaeologist during access track construction. The archaeologist monitored the removal of the topsoil and any subsoil to reveal the natural drift geology or any archaeological deposits or features. Any remains of limited extent were excavated and recorded immediately in order to maintain the work programme. Similarly, remains considered to be of particular sensitivity or at imminent risk were appropriately excavated and recorded by the archaeologist conducting the watching brief. Any discoveries which were considered to require resources beyond the immediate reach of the watching brief archaeologist (extensive and/ or complex) and sufficiently robust to survive covered under a geo-membrane were preserved *in situ* and shelved for excavation during the programme of re-instatement.

Numbers allocated to the watching brief are six digits long. The access track number is represented by the first two numbers whilst the following two numbers indicate the division of the track and the final two numbers relate to that particular context.

4.4 Excavation

Excavation of selected groups of features identified during the watching brief was undertaken during 2011. The programme of excavation was intended to work alongside the re-instatement works. This was mostly achieved with a team of three archaeologists. Context numbers associated with the excavations are four digits long ranging from 0001 to 0132. The site code for the excavations is SPN 35. Excavations were conducted on towers ZXC21 and ZXC5A, access 2701, access 2401, and access 2603 and 2605.

The excavations were carried out accordance with Network Archaeology's Written Scheme of Investigation for excavation (Network Archaeology 2010).

4.5 Metal detecting survey

The metal detecting survey commenced in January 2011 and continued throughout the project. The operator was a trained archaeologist who could identify and appropriately treat metal artefacts upon discovery. The survey was conducted on all ground before any disturbance. When it was deemed necessary, spoil heaps were also subject to the survey to retrieve any stray metal artefacts. All artefacts located during the metal detecting survey were geographically referenced with a Garmin handheld (GPS) unit.

All numbers allocated for the metal detecting survey are 6 digits long. The first two numbers refer to the access track number; the following two numbers relate to the division of the access track (see location mapping) and the final two numbers are specific to that particular context such as 400100. Most of the finds recovered from the metal detecting survey were from the topsoil.

5 Archaeological Background

5.1 Palaeolithic and Mesolithic

The Palaeolithic period covers the earliest anatomically modern humans, approximately 40,000BC, and extends to more complex groups of humans in the Mesolithic period. The Mesolithic begins with the retraction of the southernmost glacial frontier of the Pleistocene ice sheets, approximately 10,000 BC, and ends around 4,400 BC (Scarre, C 2005). The Palaeolithic and Mesolithic are not particularly well understood periods of British prehistory. The nature of the nomadic lifestyles of these ancient communities has resulted in ephemeral evidence for their daily activities (Petts, D and Gerrard, C 2006, 121).

The more frequently discovered early prehistoric remains include flint artefacts used as tools and hunting equipment. Palaeolithic flint is only very occasionally discovered in the north-east. The majority of the flint which has been found in the region pertains to the later Mesolithic period (Petts, D and Gerrard, C 2006). These flints have been found in their greater concentrations between the Tees and the Tyne close to Stanhope, Weardale and Plawsworth (Clark, P.A.G and Gosling, P.F 1976).

Although the discovery of early prehistoric settlements is rare, the north-east does boast one of the few Mesolithic houses found in Britain. The internationally significant house at Howick was a sunken floored circular building which is believed to date to 7, 800 BC (Petts, D and Gerrard, C 2006) (The Howick Project). Further settlement remains in Hartlepool, excavated by Trechmann in 1939, have tentatively been dated to the 7th millennium BC (Clark, P.A.G and Gosling, P.F 1976). A possible Mesolithic land surface has also been

identified at Darlington Bowden Doors and Goatscrag, and a possible late Mesolithic/early Neolithic ditch has been identified at South Shields (Petts, D and Gerrard, C 2006, 121).

The landscape exploited by the Palaeolithic and Mesolithic communities would have been densely wooded with an abundance of wild animals for hunting. The majority of evidence for the density and the types of woodland comes from the pollen records from Holowell Moss near Durham. This moss has been the major contributors to the palynological record for the prehistory of north-east England (Turnbull, P and Jones, R.F. J 1978, 13).

5.2 Neolithic

The emergence of permanent settlement and the advent of agriculture are commonly associated with the Neolithic period which is broadly dated to between 4,500BC and 2,250BC. Identifying the remains of Neolithic settlements and activities can prove to be difficult as these actions do not frequently leave many recognisable residues. Although the north-east of England demonstrates evidence of Neolithic occupation, these remains are less frequent between the Tyne and the Tees and locations surrounding the route of the development.

Early Neolithic settlements were deliberately sited within parts of the landscape which were conducive to the rigors of these communities' new lifestyles. The sedentary way of life adopted in the Neolithic required a shift from hunting and gathering as the main means of food procurement to the cultivation of crops and domestication of animals for consumption (Clark, P.A.G and Gosling, P.F 1976,13). The acquisition of land for animal grazing and agronomic activities would have been one of the necessary first steps for the early farmers.

Desirable land intended for settlement would require open plots of land on fertile soils which would encourage reliable crop yields. Once selected, the land was deforested, removing large swathes of forest and woodland which would have dominated the landscape (Turnbull, P and Jones, R.F. J 1978). The type of woodland coverage and approximate dates of major deforestation events can be determined by pollen remains from trees and plants which have been preserved in waterlogged deposits such as bogs and peat beds. Examples of such deposits within the region which have produced pollen cores include (Harding 1995 et al, 194) which are predominantly in the northern part of the region. The information from these pollen cores has demonstrated that deforestation occurred in isolated pockets rather than a few large scale events.

The landscape more immediate to this project unfortunately suffers from poor preservation, partially due to the wide scale damage of the lowlands and coastal areas during the 18th and 19th century quarrying and mining (Petts, D and Gerrard, C 2006, 127). This poor preservation has resulted in the absence of any pollen information pertaining to the Neolithic settlement between the river Tees and the Tyne (Turnbull, P and Jones, R.F. J 1978).

The paucity of environmental remains, such as pollen, within the south Durham lowlands is reflected by the archaeological evidence. There have been very few settlement remains in the Tyne/Tees corridor (Clark, P.A.G and Gosling, P.F 1976, 21). The majority of the Neolithic settlement within the region is again echoed by the environmental evidence clearly displaying a clear preference for settling the northern coal measures and the Millfield Basin in Northumberland and the Cumbrian hills (Clark, P.A.G and Gosling, P.F 1976). Domestic structures like the ones found at sites such as Thirlings and Old Yeavering are often characterised by a series of pits and post holes which may be diffusely distributed or ordered in a rectilinear arrangement (Clark, P.A.G and Gosling, P.F 1976, 16). Concentrations of finds such as pottery and worked flint may also allude to the location of Neolithic settlements.

The earlier Neolithic settlements would have been a mélange of small isolated farmsteads. Geographical boundaries of larger communities would have been delineated by natural features such as water courses, as well as deliberately constructed monuments (Pollard 2009). In the later Neolithic, the cairn fields in the Millfield basin in Northumberland may have supported an extended population. Unfortunately the ephemeral nature of Neolithic settlement

and the fact that the landscape has been re-worked throughout the subsequent periods of history leaves little evidence of such settlement.

Typical types of materials frequently associated with this period include flint artefacts, similar to those used by the Mesolithic communities. Langdale, in Cumbria, is regarded as one the most prolific producers and distributors of finished flint artefacts. The 'flint factory' would have been in operation at the beginning of the 4th millennium BC and would have produced axes, pikes and sickles. Fragments of these artefacts from the Langdale flint factory have been discovered in Weardale and on the magnesian limestone between the Tyne and the Tees (Clark, P.A.G and Gosling, P.F 1976, 21). Although small amounts of worked flint is frequently found as 'background noise' within the topsoil, higher densities of flint may suggest trade networks, settlements or flint working platforms. Such fragments of un-worked flint and worked flint artefacts have been recorded close to Raisby Hill Quarry and to the south of Garmondsway during refurbishment of the existing Spennymoor to Norton overhead line. A scatter of worked flints and a separate single flint artefact have been recorded within the vicinity of Grindon. Other discreet flint finds have been found close to Fulthorpe and Wynyard Park.

At approximately the same time as the 'axe factory' in Langdale was in full production, early pottery such as Grimston ware was being produced (world timelines.co.uk). A succession of new pottery types came to fruition through the Neolithic and culminated with Beaker wares in the transition of the Late Neolithic to the Early Bronze Age. The amount of Neolithic pottery which has been found within the region pre-dating the advent of Beaker pottery is extremely low. Most pottery has been found in Northumberland and has been rarely recovered on the magnesian limestone escarpment between the Tyne and Tees.

The appearance of monuments constructed out of earth and stone is a phenomenon associated with the emergence of the Neolithic ritual landscape. The earlier of these monuments are the causewayed enclosures and un-chambered long mounds and chambered tombs (Scarre 2007, 82; Cummings in Pollard 2009). Causewayed enclosures are a class of monument which is not usually found in northern England. Despite their scarcity in northern England, a possible causewayed enclosure has been identified through aerial photography at Flodden Hill in Northumberland. The interpretation of this earthwork has not been confirmed by excavation.

In the later Neolithic period, monuments of various distinctions became more prominent. Burial monuments such as cairns and long barrows are constructed as physical reminders on the landscape intended to emboss the memories of the ancestors into everyday life. A possible Neolithic burial mound has been discovered at Coffee Pot Plantation close to Bishop Auckland and a long cairn in the western region of county Durham in Irehopeburn has been identified (Turnbull, P and Jones, R.F. J 1978).

The excavation of a Bronze Age round barrow at Hasting Hill, Sunderland, identified an earlier burial interred underneath the barrow which has been carbon dated to 2,890BC, firmly placing it in the late Neolithic period. Two round barrows believed to be either Bronze Age or Neolithic have also been identified in Warden Law (Clark, P.A.G and Gosling, P.F 1976).

The end of the Neolithic period is marked by the emergence of metals and new technologies. There are distinct changes in the dynamics of the societies and the ways in which people live their everyday life, and the way they are ultimately treated upon their death is noticeably different.

Further evidence for Neolithic activities from the wider region can clearly be seen at How Tallon, where the boundary between Yorkshire and Co Durham on Barningham Moor is scattered with round barrows and a Cairn (Burl 2005).

The changes in people's lifestyles, beliefs and economies through the transition between the Mesolithic and the Neolithic are poorly understood. Casual finds and excavations on the lowlands between the Tyne and the Tees do not particularly contribute to a wider understanding of this topic. The amount of stray flint finds discovered around the route of the

development does suggest that whilst there was not the same level of permanent settlement, such as on the northern coal measures, there was a certain sustained amount of activity. The amount of settlement activity appears to have gradually increased around the transition between the Neolithic and the Bronze Age.

5.3 Bronze Age

The Bronze Age is broadly dated between 2,250BC and 800BC. Along with the advent of metals, the use of monuments to inter and commemorate the dead results in heightened levels of material culture discovered during this period of prehistory. Rock art on Barmington Moor and Northumberland also add to the distinct character of Bronze Age activities in the north east. The intensification of settlements and the amount of land cleared for crop production and animal husbandry also occurs in the Bronze Age.

The agricultural economy of the Late Neolithic continued unabated into the Bronze Age. Hundreds, and in some cases, thousands of years of sedentary life of the early farmers had evolved and changed their methods and techniques. By the Bronze Age, farms had become larger requiring more open farm land. Pollen evidence from Bishop Middleton, 5km south-east-south of Ferryhill, suggests that there was large scale woodland clearance and intensified cereal production in 1,400BC (Turnbull, P and Jones, R.F. J 1978, 13-14 and Bartley, Chambers and Hart Jones 1976). The same model of clearance followed by cereal production can be seen at other sites such as Mordon Carr and Neasham Fen. With the exception of these sites, there has been very little evidence for the cultivation of cereals associated with settlements on the magnesian limestone escarpment. This use of the landscape for agricultural practices continued until the end of the Bronze Age when there is evidence for large scale forest clearing.

The appearance of what we today recognise as a field is regarded as a Bronze Age innovation. Neolithic field systems are scarce. This may be because physical boundaries were not created or have been destroyed by subsequent activities (Pryor 2006). Neolithic fields in Northumbria were possibly delineated by stones cleared from the fields (Johnston in Pollard 2009). In some parts of Britain, such as the Thames Valley and the East Anglian Fens, large systems of coaxial field systems and droveways would have enclosed large parts of the landscape. These field systems would have been constructed from ditches and hedges. Existing boundaries observed in the Neolithic delineated by monuments may have been maintained and become part of the later landscape (Pryor 2006).

Bronze Age settlement activity was again proportionately much higher in the Cheviots and fell sandstone than the magnesian lime escarpment (Petts, D and Gerrard, C 2006). The evolution of the upland settlements and how the landscape changed are altogether much better understood (Petts, D and Gerrard, C 2006, 129). Palisade enclosures have been discovered at Fenton Hill near Wooler and underneath the Roman fort at Corbridge.

Little evidence for Bronze Age settlement has been discovered on the magnesian limestone between the Tyne and the Tees. The absence of typical Bronze Age landscape features such as large field systems does suggest that the farmers in the lowlands would have grazed their animals within natural forests without clearing, and were probably living in dispersed settlements (Turnbull, P and Jones, R.F. J 1978).

The types of buildings expected to be found within Bronze Age contexts would have had a circular footprint. The physical remains of such buildings are often found as a circular arrangement of post holes or a penannular ditch which would have acted as a drainage gully (Harding, D 2009). Examples of such houses can be seen at West Brandon, Esh and Brancepeth. These settlements are all believed to be Iron Age but some of the structures or elements of the settlements such as boundaries may be Bronze Age (Turnbull, P and Jones, R.F. J 1978, 14).

Funerary monuments continued to be built through the Neolithic and into the Bronze Age. A more common funerary monument in the Bronze Age would have been the round barrow, a

circular mound of earth with a circular ditch surrounding it and at least one body interred within the mound. Round barrows do, on occasion, survive as visible upstanding earthwork mounds. Unfortunately many of these have been 'ploughed out' in an attempt to create more farmable land. The absence of the upstanding mound means that in most cases the only remains of these features are the circular ditch which surrounded the mound. These circular features can be identified as a cropmarks from aerial photographs. A series of circular cropmarks have been recorded from such aerial photographs in the 1970s in the area between Coxhoe and Cornforth all located close to the Coxhoe Beck (Jones 1977). As there are no formal excavations to confirm the interpretations of these features, they may be relating to later activity such as quarrying or ancient watercourses.

Two further sites of ring ditches have been identified through cropmark analysis. The first of these comprises five annular or penannular cropmarks along the southern bank of the Coxhoe Beck. The second of these comprises further ring ditches possibly representing the sites of barrows at Catley Hill to the west of Trimdon. Both of these proposed sites may have formed part of a wider series of Early Bronze Age funerary monuments to the south of the current route of the Coxhoe Beck.

A barrow at Trimdon Grange was the focus of antiquarian excavations in the 19th century (Petts, D and Gerrard, C 2006). A burial cist believed to belong to the later Bronze Age and containing five inhumations was found at Kelloe Law Farm in 1948 (Turnbull, P and Jones, R.F. J 1978). The Tyne-Tees region has far less Bronze Age burials and remains than surrounding areas like Cumbria, Northumberland and Yorkshire (Clark, P.A.G and Gosling, P.F 1976).

Beyond the use of funerary monuments to dispose of and commemorate the dead, the practice of cremation becomes prominent in the Late Neolithic and throughout the Bronze Age. Fragments of cinerary urns have been discovered at Trimdon (Clark, P.A.G and Gosling, P.F 1976, 23).

Aerial photographs taken as part of the current project have identified cropmarks of another ring ditch some 25m in diameter to the east of Grindon. A second possible ring ditch of similar size may also be present just to the north-east.

The appearance of nationally significant rock art is attributed to the Late Neolithic/Early Bronze Age. Rock art is not an isolated expression; many of the examples of rock art exist in conjunction with other monuments within the landscape (Petts, D and Gerrard, C 2006). Examples of rock art can be seen in several places around Barningham Moor and one of the best resources for rock art in the UK can be seen in Northumberland (Petts, D and Gerrard, C 2006, 128-133).

Before the casting of bronze, copper was the brief forerunner. Copper was the first metal to be worked but is rarely discovered in archaeological contexts within the British Isles and is not thought to be domestically produced. The casting of bronze was developed in the British Isles relatively late when compared to the rest of Europe. Once bronze casting had become established, the occurrence of bronze artefacts becomes more common. One of the earliest types of artefact that was casted out of bronze was the axe. An example of one of these axes was found to the south east of Coxhoe, immediately to the east of the A177.

Flint continues to be worked and shaped into tools. Fragments of worked flint dating to the Bronze Age have been found to the south of Garmondsway. A flint arrowhead and a stray worked flint have been found near Thorntree Farm.

There were communities on the lowland magnesian limestone which continued to develop the landscape but at a lesser extent than the uplands. Nevertheless, the chronologies of many of the settlements on the uplands and lowlands are poorly understood. More excavation and better dating techniques in the future will hopefully tighten the chronologies (Petts, D and Gerrard, C 2006, 129).

5.4 Iron Age

The Iron Age is the final period of British Prehistory. It is traditionally dated from 800 BC, with the advent of iron materials in British contexts such as the Llyn Fawr hoard, and culminated at the Roman Conquest in 43 AD.

The settlements of the tribal communities in the north-east, believed to be the Brigantes, would have been a mix of dispersed enclosed and unenclosed settlements.

There is a growing body of evidence for increased levels of settlement during the Iron Age. Both enclosed and unenclosed settlements such as Ingleby Barwick and Thorpe Thewles can be seen to develop and prosper across the region. Many rudiments of these settlements and patterns of domestic organisation found within County Durham and Teesside Iron Age contexts appear to be broadly similar to those encountered within contemporary examples across the majority of Northern England.

Many settlements from the Bronze Age continue into the Iron Age. The overall distribution of many of the later Bronze Age settlements is very similar to the Iron Age sites (Clark, P.A.G and Gosling, P.F 1976, 28). Many of the palisade enclosures witnessed in the Bronze Age change during the Bronze Age/Iron Age transition were adapted into hillforts (Clark, P.A.G and Gosling, P.F 1976, 24).

Hillforts were essentially defended hilltop settlements. Within these settlements it was common to find round houses and ancillary storage structures. The defensive facets of the settlement would have been in the form of at least one large ditch and bank and may have used timber ramparts to enforce the bank (Darvill 1987). Examples of hillforts in county Durham include Shackleton Beacon Hill near Redworth, Toft Hill near Bishop Auckland, Stockley Beck in the Brancepeth Parish, and Maiden Castle south of Durham (Petts, D and Gerrard, C 2006, 139 and Clark, P.A.G and Gosling, P.F 1976, 24). Many more hillforts are known to exist to the north in the Coquet and Breamish valleys (Discovering Our Hillforts Heritage Project). The amount of hillforts in the Coquet and Breamish valleys suggests that there was a significant political or cultural boundary, possibly delineated by the Tyne.

A class of settlement which is common in the north-east of England is the enclosed settlement. The purpose of an enclosed settlement is the protection of the settlement by the inclusion of a ditch and bank around the perimeter of the settlement. Typical enclosed settlements identified in the region are both rectangular and sub-circular. These have largely been recognized by the extensive research of George Jobey (Petts, D and Gerrard, C 2006, 138). Rectilinear ditch enclosures have been identified at Brancepeth, Esh, North Finchale, Etherley, Croxdale, Hartburn, Burradom, Wickham, Brawns, Thorpe Thewles, Den, Broomsdale, and Thornley (Petts, D and Gerrard, C 2006, 138 and Clark, P.A.G and Gosling, P.F 1976, 27). The majority of these settlements are located to the north of the Tyne suggesting the continued preference for settling on the coal measures.

There are several enclosure sites believed to be Iron Age in date within the vicinity of the development. These include a possible earthwork enclosure near Coxhoe Bridge, and a cropmark of a possible Iron Age square enclosure (variously recorded as Harap Hill, Fishburn or Harup, Trimdon) to the west of Trimdon. Further similar enclosures have been observed between Thorpe Larches and Grindon Grange with a crop mark to the south of Thorpe Thewles.

The variety of settlement variation in the Iron Age is demonstrated by the array of settlements in the region which do not display a surrounding bank and ditch. These unenclosed settlements have been identified at Holburn Wood, Plawsworth, and Ingleby Barwick (Petts, D and Gerrard, C 2006, 138).

Beyond the obvious physical differences of the enclosed and unenclosed settlements, little else is known. The differing functions and statusus of the inhabitants is difficult to glean due to the limited excavation of the sites and the low frequency of finds. Increased use of

thermoluminescence dating of pottery may assist in the greater understanding of the dating of settlement types which would in turn assist in creating a chronology for settlement morphology and function (Petts, D and Gerrard, C 2006, 136-7).

All settlements pertaining to the Iron Age appear to be distributed in greater numbers to the north of the Tyne and are in greater numbers to the east than the west (Clark, P.A.G and Gosling, P.F 1976, 24-28). With the exception of Thorpe Thewles, Hartburn, West Brandon, Coxhoe and the possibility of Garmondsway, there has been little evidence for Iron Age settlement in the immediate vicinity of the development.

The presence of the forts at Piercebridge near Darlington *(Magin/Morbium,* South Shields *Arbeia*, Ebchester *(Vindomora*), Lanchester *(Longovicivm),* Chester le street (*Concangis)*, Binchester within Teesside, and County Durham do suggest that there may have been a larger presence of Iron Age communities in the Teesside and County Durham area than the evidence suggests (Clark, P.A.G and Gosling, P.F 1976, 32).

The increase in population required a greater quantity of land for food production as well as settlement. Most of the landscape was cleared by the Iron Age/Romano British period (Clark, P.A.G and Gosling, P.F 1976). Evidence for the variety of crops grown has been identified on the magnesian limestone escarpment including cereals and hemp.

The earliest examples of iron discovered in Britain are all imported from Europe. Bowl furnaces in the south east of England are the earliest recognisable domestic iron furnaces. Once production had been established by the use of bowl furnaces, iron production gathered momentum and after the introduction of slag tapping furnaces, high quality iron became more available (Ehrenreich 1985, 87). By the end of the Iron Age, La Tene style iron weaponry was been deliberately deposited as a votive offering in British contexts. Very little evidence for iron working has been discovered in the region. This may be due to low production of iron or the repeated action of re-cycling which is one of the advantages of iron as a material.

Very little is known about the chronologies of late prehistoric pottery in the region (Petts, D and Gerrard, C 2006). This is due to a general paucity of pottery remains which have been discovered on late Bronze Age and Iron Age sites.

There has been little evidence for the role of industry in the land between the Tees and the Tyne. An example of the rare evidence for salt production has been discovered at Coalham Marsh on the mouth of the river Tees (Petts, D and Gerrard, C 2006). The role that the production of salt played in Iron Age Britain is still relatively ill-understood (Darvil 1987).

5.5 Romano British

At the time of Roman contact with Britain, the project area was under the control of the Brigantes, who dominated a vast area of Northern England. The Brigantes may have been a confederation of smaller tribes, who typically built small fortified hill crofts and relatively small enclosed settlements (such as at Thrope Thewles). Initially the Brigantes welcomed Roman influence in Britain, becoming a client kingdom in the first half of the 1st century AD. Relations became strained in the following decades and by AD79/80, Agricola had pushed his forces north of the Tees and crushed any signs of revolt. Once Hadrian's Wall was constructed in 122AD, Brigantian territory lay firmly under Roman influence, with the movement of people and goods controlled by limiting access through the Wall except at manned gates. Roman influence would have expanded outwards from forts, milecastles and new settlements as Brigantian farms were encouraged to deliver to these new markets, plausibly absorbing Roman goods in exchange.

Periods of peace in northern eastern England were short lived. The Roman civil war at the end of the second century was a major drain on military resources and resulted in a shortage of soldiers in Britain. After the civil war there was 10 years of peace in northern England and the reluctance of many indigenous communities to indulge in typical Roman activities and styles appears to have been partially abandoned (Millett 1992). This peace did not last and the

barbarian conspiracy in AD 367 unsettled the already weak administration of the late Roman 4th century and by AD 400 the Roman army officially withdrew from Britain.

The established way of life, which for the most part had remained broadly similar since the end of the Neolithic was threatened by the expansion of the Roman frontier. The dynamics of settlement had changed from the dispersed settlements of the early farmers to a much more nucleated arrangement of enclosed settlements and hillforts. Part of the package of new innovations that the Romans transmitted across the empire was the *vici* and town.

Vici were towns which developed around the forts. The influx of soldiers and associated staff facilitated a peripheral economy all of their own. Workshops and kitchens would have been established around such military installations by the native populations to financially profit from the relatively wealthy soldiery. The *vici* would have steadily grown, accommodating auxiliary soldiers and their families as well as the craftsmen and workers. Once the fort had gone out of use, the *vici* may have continued and developed into a larger town or may have dwindled without the support of the fort. Examples of *vici* can be found close to Piercebridge, Corbridge, York and Vindolanda forts (Clark, P.A.G and Gosling, P.F 1976, 35- 36). Some *vici* continued to prosper and developed into defended walled settlements. These include Kirkby Thorpe, York and Carlisle.

A typical facet of the Romano British landscape would have been the villa. Villas have been identified at Holme House, Old Durham, Faverdale and Quarry farm (Turnbull, P and Jones, R.F. J 1978, 17; Petts, D and Gerrard, C 2006, 148).

Both the *vici* settlement and the villas represent a more typically Roman way of living. There was a large contingent of the indigenous population which continued to live in the same way as the Iron Age communities had (Turnbull, P and Jones, R.F. J 1978, 17). This can prove to be difficult for archaeologists to distinguish between a pre Roman conquest settlement and a post conquest settlement as there is no cultural difference.

Some of the larger indigenous settlements which grow and prosper in the Roman period include Faverdale, Ingleby Barwick and Sedgefield East Park and Catcote (Petts, D and Gerrard, C 2006, 134). These settlements are all to the west and north of the development, while to the east along the coast between the Tyne and the Tees settlement appears sparse compared to Yorkshire and Northumberland (*ibid*). The relationship between the rural communities which continued in the indigenous way of life is poorly understood. Future work may reveal more about the dynamics of these relationships (Petts, D and Gerrard, C 2006, 150).

The adoption of Christianity in the Roman period may have originally been within the forts and *vici.* Travelling soldiers from across the Empire would have brought elements of the religion which would have gradually percolated into the indigenous population (Petts, D and Gerrard, C 2006, 152).

The relationship between the indigenous populations of northern England and the expanding Roman frontier is obscure (Clark, P.A.G and Gosling, P.F 1976). The placement and development of Roman forts and military installations can be used to allude to areas which were likely to be influenced by the Roman military.

Forts located in the Tyne-Tees corridor include South Shields (*Arbeia)* which began construction in AD 163, Piercebridge near Darlington *(Magin/Morbium)* built in the late third century (Clark, P.A.G and Gosling, P.F 1976, 34) Lanchester *(Longovicivm)* built sometime in the Hadrianic period AD 117-138, Binchester, Ebchester *(Vindomora)* built between AD 69 to AD 117 and Chester le street (*Concangis)*, built in the late first on early second century BC, all in County Durham. With the exception of the few hillforts between the Tyne and the Tees there was little to suggest overt rebellion from the native population. The high amount of forts in the area may suggest that there was more than a single military strategy in place with the positioning of the forts (Petts, D and Gerrard, C 2006). There is a suggestion that the forts

may have facilitated a certain level of urbanisation which later became indigenous administrative centres.

Forts to the north of the River Tyne include Corbridge *(Corstopitvm/Coriosopitvm)*, built in the first or second century Wallsend, Vindolanda and Stanegate (Turnbull, P and Jones, R.F. J 1978, 15). These forts existed in one way or another for over three centuries.

Both Hadrian's and the Antonine Wall are World Heritage sites. The first of the walls to be constructed was Hadrian's Wall in 122AD. The wall extended from the east coast to the west coast and displayed impressive mile castles and turrets. A decade after the completion of the wall, a second wall between the forth and the Clyde was commissioned by Emperor Antoninus Pius and constructed in the 140s AD. The Antonine wall was under constant pressure and abandoned by 160AD, with troops falling back to the more defendable Hadrian's Wall, which was manned until at least the late 4th century AD. The Hadrian's Wall Research Framework which includes Tim Gates' aerial survey has highlighted how well conceived and executed aerial surveys can locate and map sites (Huntley et al 2007).

Although there were roads in Britain before the Roman conquest, the Romans were accredited with the formalisation of the road system. There are two roads which proceeded north to south between the Tyne and the Tees, Dere Street and Cades Road. Cades Road is the closest known Roman road to the route of the development and crosses the route close to Coxhoe where there is a noticeable turn to the west.

Cades road would have run from Brough-on-Humber (Petuaria) to Newcastle, passing to the west of Thorpe Thewles (Margary 1973). The road would have passed close to the West House enclosed settlement at Coxhoe, before crossing the Wear Valley. Parts of the route of Cades road are poorly understood and it has no named corresponding Roman road has been found (Petts, D and Gerrard, C 2006, 146). The development of the medieval settlement at Garmondsway may be attributed to the close proximity to the Cades Road (Clark, P.A.G and Gosling, P.F 1976, 34).

The final decades of Roman occupation in Britain and the century after the Romans leave are poorly understood. The level of stability and continuity within the towns and forts is difficult to determine due to poor dating and issues with identifying the difference between the Roman era occupation of forts and *vici* and post-Roman continuity (Petts, D and Gerrard, C 2006, 153).

5.6 Early medieval (5th-10th Century AD)

This period is marked by a limited amount of archaeological data, particularly securely stratified sites and accurate scientific dating. This is exasperated by the shifting political borders, invasions, border and sea raids and migrations of peoples which give northern England its distinctive character. Conversely, there is a reasonable level of historical sources for the period, mainly provided by the ecclesiastical communities which emerged in the north-east in the early medieval period.

The Roman Empire began a terminal decline in the late 4th century as increased incursions from hostile cultures, notably the Visigoths, forced Rome to begin withdrawing troops from the fringes of the Empire to defend home territories. By 399 AD, troops began to leave Britain and by 400 AD, when the Visigoths sacked a weakened Rome, there were few soldiers left on the borders, other than those who had settled in Britain. Although Rome and the Visigoths agreed a treaty soon afterwards, Roman influence in Britain was diminishing and frontiers were left exposed to revolt and raids. North-east England was particularly exposed on two major fronts, to the north notably from Scots and Picts and the east where an expanse of previously defended coastline allowing access to continental Europe and Saxon and Angle raiders. Anglo-Saxon settlement can be noted north of the Humber by 450 AD and the proto-kingdom of Deira became established.

By the 5th century there were well established field systems in some part of the region, largely hangovers from the Roman occupation. In other parts of the region such as the lowlands around the Tees valley, parts of the landscape were abandoned (Dunsford, Roberts and Harris in Liddy and Britnell 2005). During this abandonment, any cleared landscape is believed to have returned to open woodland and shrubs. The returning wilderness did not last long and is thought to have been returned to agricultural land soon after the 7th century. The absence of well dated pollen cores from the lowlands unfortunately means that an accurate date cannot be attributed to this event (Petts, D and Gerrard, C 2006). This suggests a period of depopulation and regression from cultivated land, which may have been expected in the initial years after the exodus of Roman influence.

Despite the difficulties posed by the degree of interpretational uncertainty, excavations at Roman forts such as South Shields and Birdoswald suggest that the forts do continue into the 5th century but are not occupied throughout the transition into the 6th century, perhaps suggesting a decreased importance to defence or a breakdown of established military groups. Excavations at Norton on Teesside indicate an Anglo-Saxon presence by the mid-late 5th century AD implying a steady migration north of the Humber by the Angle and Saxon settlers. An important 5th-6th century Anglo-Saxon cemetery excavated at Norton, revealed over 100 burials, some with weapons and grave goods donating status, with the cemetery re-using Roman boundary ditches (Rowe 2000). This suggests settlement had reached the boundary of the study area shortly after the Roman period, implying steady migration and a constant population warranting a large cemetery.

Gildas, writing in the 6th century, suggests that agreement was reached between Britons and Anglo-Saxon mercenaries or federates to settle in north-east Britain and contain the threat from the northern border, effectively creating a new strong border by approximately 480 AD (Dumville, D 1989). This northern part of Britain lying between the Scots and Picts and Deira became known as Bernicia. Bede, writing in the early 8th century, describes the detachment of Deira and Bernicia from Romano-British control, effectively becoming separate kingdoms controlled by powerful Anglo-Saxon settlers in the 6th century. In 547, Ida the Flame bearer, a powerful Angle chief seized the historic coastal stronghold of Bamburgh and added territory around the Tyne, Wear and south of the Tees to his burgeoning kingdom. Bernica was retained by Ida's family, though was tested for decades by incursions from British tribes in the west and the Scots and Picts from the north. By 593 Aethilfrith, Ida's grandson, held Bernicia and in 598 he defeated a large combined army of Britons at Catterick. For the next few years, Aethilfrith consolidated his power and finally usurped the kingdom of Deira, uniting all Angle land north of the Humber to form the basis of the kingdom of Northumbria in the early 600s, at this point modern Teesside and Durham would have lain near the centre of this Kingdom.

Despite unification, the north-east remained turbulent throughout the 7th century AD. Aethilfrith was killed in battle by Raedwald of East Anglia in 616 barely a decade after unifying the kingdoms. Edwin, son of the former king of Deira took the throne and once again made Northumbria a major power, including defeating an army of West Saxons in Wessex, arguably making Edwin overking and Northumbria the most powerful Kingdom in Britain at the time. Edwin converted to Christianity in 627, partly in order to maintain relations with the Kent Anglo-Saxons, to whom he was due to be related in marriage through Princess Ethelberga. Edwin was baptised at St Peter's in York by the Roman Christian missionary Paulinus who was soon engaged as Bishop of York and travelled throughout the kingdom converting Northumbrians. St Peter's was rebuilt in stone at Edwin's order and would later become the site of York Minster. Edwin's rule as a the first Christian King of Northumbria would not last long; he was defeated and killed in 633 by the combined forces of Cadwallon ap cadfan, King of Gwyneth and the Mercian chief Penda, at the Battle of Hatfield Chase.

The new kingdom was broken back into Bernicia and Deira following Edwin's defeat until Oswald, the younger son of Aethilfrith, returned from exile on Iona and defeated Cadwallon near Hexham in 634. Oswald was soon recognised as King of Northumbria and like Edwin,

chose to support the Christian faith, including bringing Aidan, an Irish monk (later St Aidan) over from Iona to found a monastery on Lindisfarne. Oswald, like Edwin, expanded the power of Northumbria, bringing the Lothian area of modern Scotland under his control and seizing Edinburgh, fortress of the Gododdin. Oswald's expansion was brought to an abrupt end in 642 at the Battle of Maserfelth, by an army again led by Penda, now King of Mercia.

Oswy, Oswalds brother, took the Bernician throne, while a rival, Oswine, seized control of Deira; Penda having also made a land grab in to Deira as a result of his recent victory. The following years were often violent with Mercia and a split Northumbria almost at civil war. By 655 matters had been resolved in Oswy's favour. Oswine had been murdered at Catterick by Oswy's men and Penda and many of his chieftains killed in battle near Leeds. Oswy took control of all of Northumbria and parts of Mercia. By the time of Oswy's death in 669 and through the remainder of the 7th century Northumbria controlled a huge area and was arguably the foremost Kingdom in Britain.

The modern towns of Hartlepool, Newcastle, Durham and Darlington are believed to have their roots in this period (Petts, D and Gerrard, C 2006). There appears to be diversity in settlement typologies in the 7th and the 9th centuries. This may be a result of status as well as ethnicity and political allegiances (Turnbull, P and Jones, R.F. J 1978). There is a noticeable absence of settlements within the proximity of the development. The deserted village of Garmondsway may have originally been settled in this period, though dating is tenuous. The establishment and expansion of major settlements, known to have existed near modern day towns such as Yeavering, Seaton Holme, Bamburgh, Bishop Auckland and Simy Folds also may have been started in this period (Petts, D and Gerrard, C 2006 and Turnbull, P and Jones, R.F. J 1978). However, there is little understanding of settlements outside of these more powerful centres (Turnbull, P and Jones, R.F. J 1978). With the exception of Hartlepool, very little evidence for settlement has been found in any proximity to the development or the river Tees (Clark, P.A.G and Gosling, P.F 1976). It is believed that during the reign of King Oswald in the 7th century the land between the Tyne and the Tees was a 'wilderness inhabited only by beasts' (Turnbull, P and Jones, R.F. J 1978).

Large monastic sites such Monkwearmouth Lindesfarne and Jarrow were built towards the end of the 7th century and were major centres of learning, with well-travelled scholars adding to their growing library. King Oswy's sister, Ebba is also believed to have founded Urbs Coludi (Colud's Fort in Berwickshire) in AD 660 (Turnbull, P and Jones, R.F. J 1978). Further evidence for the scale in which Christianity became the dominant faith and the gaining influence of the church is demonstrated at Escomb. This church is one of the most complete examples of a church from this period in England. There is clear evidence for the use of stone from the nearby fort at Binchester in the church (Gelderd 2008).

In 692, Bede, a scholar at Jarrow monastery was ordained a Deacon at just 19 and by 703 was a fully ordained priest. Bede was perhaps the most notable British writer of the age, producing several important texts including his History of the English Church and People, completed in 731 and detailing Anglo-Saxon history from the preceding centuries. Bede's work is still one of the most important historical documents for this period. Bede's influence with the church was sufficient for the Pope to elevate York to an Archbishopric, making it independent of Canterbury for the first time and further endorsing Northumbria's status as a powerful Kingdom. During this time Northumbrian monasteries were producing fantastically decorated books such as the Codex Amiatinus, an early illuminated bible made as a gift to the Pope.

Whilst the 8th century was notable for the growing power of the church and the scholarship of Northern monasteries; politically the Kingdom was growing weak as the Royal houses of Bernicia and Deira openly rebelled into civil war. Between 737 and 806, Northumbria had ten kings, three of which were murdered, five exiled and three who became monks. Amongst this background of instability, Viking raids along the coast began at the end of the 8th century.

Viking raids targeted the wealthy monasteries, often conveniently accessible by boat. The great house of learning and Christianity at Lindisfarne was raided in 793, robbing and killing

many of the monks, which shocked Europe, causing Charlemagne's court to describe it as God's vengeance for the lack of morality in Northumbria. Over the next few decades, raids would be targeted against the major monasteries of Lindisfarne (again), Jarrow, Hartlepool, Whitby and Tynemouth. The monks began to flee the coastal monasteries and move inland in search of safer places of worship as it became clear Northumbria could no longer be sure of defending its coastline.

In 829, Eanred the latest king of a weakened Northumbria was forced to accept Egbert, King of Wessex as overking of England, formally acknowledging the transfer of power from Northumbria to Wessex, where it would remain until 1066. Eanred and his descendents clung onto power throughout the decades of Viking raids until in 866 a Danish army travelled from the Low Countries under the command of Ivar the Boneless. York was taken that winter despite its defences and the Northumbrian King Aelle, captured trying to relieve the city. The Danes brutally executed King Aelle and installed Egbert as a puppet ruler. As the Danes consolidated power by claiming Mercia, they settled across Deira, in modern Yorkshire and parts of Lancashire. In 875, Halfdene, Ivar's brother, declared himself the first Danish King of Northumbria, quelling any rebellions and chose York as his capitol, ignoring the old power of Bamburgh. Danish influence appears to have been relatively subdued in Bernicia, beyond a few notable place names and the settlement at Tynemouth used to control the Tyne and as a stopping point for coastal ships. Bamburgh was retained in Anglo-Saxon hands, though they were now only allowed to be High Sheriffs, no longer Kings. Halfdene's son, Guthred became King in 877 and was a more moderate ruler, allowing the creation of a new area in southern Bernicia for the Christian population, including a number of displaced monks, between the now Danish controlled Deira and northern Bernicia, which retained a largely Anglo-Saxon population. This new area lay between the Tyne and Tees, centred at the old Anglian church at Chester-le-street and would eventually become a new Bishopric encompassing the modern county of Durham and much of the study area.

The 10th century witnessed destabilisation again, as the Danish and Anglo-Saxon kings fought over land. Viking settlers in Ireland led by King Ragnald attacked Northumbria, capturing York and making it a client kingdom subject to Dublin. Ragnald also seized land from the Bishopric of Durham to give to his supporters including land at Billingham, School Aycliffe and parts of the east coast between Hartlepool and Sunderland. Over the next decades Anglo-Saxon armies from Wessex would fight against the Danes and Scots for control of the North. York changed hands between the Wessex and Viking Kings several times. The Scots saw an opportunity to advance their own claims and raided Northumbria as far as the Tees, finally claiming back Edinburgh, with an eye on claiming northern Bernicia and their old territory of Lothian.

By 955 Northumbria was back in Anglo-Saxon hands as Edgar, overking of Wessex, took control of the country backed by powerful regional earls. The Scots under King Malcolm would frequently raid into Bernicia, through their former land of Lothian and past the Tees, though the threat of a combined Anglo-Saxon army including Danish settlers was enough to defy outright war, it left the northern Kingdom ravaged. This was exasperated when Viking raids recommenced along the Northumbrian coastline, once again targeting monasteries. Monks from Chester-le-street fled to Ripon for safety in 995 and when the dangers had passed set up a new community in the better defended Dunholm (modern Durham) rather than return to Chester-le-street. King Malcolm continued to raid deep into Bernicia, including reaching as far south as Durham City, where they were defeated. However, the threat from the north was more apparent than ever and a weak Northumbria was heavily exposed, and further ravaged as plague rolled across the Kingdom in the 10th century.

5.7 Later medieval (11th-16th Century AD)

The later medieval period in the north-east again shows little archaeological evidence for the time prior to the Norman Conquest, though there is again historical data. The early 11th century starts much as the preceding ones, with a Viking army again landing in England, this

time defeating the Wessex armies and putting a Danish King, Swein Forkbeard on the throne. The next few years were chaotic with Swein dying only months after taking the throne and warring Anglo-Saxon and Dane factions again contesting the throne. By 1016, Canute, Swein's son, had claimed the throne and married into the previously ruling Anglo-Saxon family.

Canute separated England into Earldoms, installing Danes as Earls of Northumbria and York. The Bishopric of Durham was however flourishing, and incorporated more territory under his control including land near Sedgefield. Stockton on Tees and Norton were both passed into Dane hands. Dane rule in Northumbria suffered a major blow in 1019, when Malcolm finally claimed back Lothian and also grabbed all the land north of the Tees. Canute continued to patronise the Bishops of Durham by gifting them land at Staindrop and their power waxed, with Canute allegedly walking barefoot from Garmondsway to visit St Cuthbert's shrine at Durham. Northumbria remained in Dane hands, and prior to the conquest, the Danes were involved in a tit-for-tat border struggle with the Scots

Following the Norman Conquest of 1066, the north initially remained in Viking and Anglo-Saxon hands, with King William leaving many Danish or Anglo-Saxon earls in place, while rewarding his own men with new titles. However the North chafed under Norman rule and by 1069, King William's appointed northern earls were murdered and the Norman garrison at Durham slaughtered by a combined force of Anglo-Saxons, Danes and Scots. William retook and wintered at York, before beginning his infamous campaign 'Harrying of the North'. Northumbria was methodically ravaged; crops burnt, houses destroyed and any rebellion brutally crushed. The outcome was a famine in Yorkshire, with Simeon an 11th century chronicler at Durham describing no village left inhabited between York and Durham, the land becoming 'lurking places for wild beasts and robbers' (Tees Archaeology nd). Simeon described the famine as being such that survivors were forced to eat cats, dogs, and horses and even adopt cannibalism. Without people to work the damaged fields, they fell fallow and rapidly regressed to wilderness. The Norman army also took the opportunity to sack Durham, taking many of their religious treasures. Orderic Vitalis, a monk writing in the early 12th century at Shrewsbury wrote that William left the North to starve to death.

The following years saw a series of raids from the Scots north of the border and Norman troops coming from York, all ravaging the land north of the Tees, with both sides seeming to rob and pillage without much discrimination. An indication of this desolate wasteland or perhaps simply its dangers can be seen in the Domesday survey of 1086: the survey does not extend north of the Tees.

By 1091, William St Carileph was restored as Bishop of Durham following exile and given royal prerogative to purchase political land rights. William becomes the first 'Prince Bishop' having a vast amount of autonomy and acting as lesser king in the North.

By the end of the 11th century, Malcolm III of Scotland had been killed in a failed raid at Alnwick and a truce was declared between England and Scotland. Northumbria has been reduced to Northumberland stretching from the Tweed to Tyne, though parts of Durham were retained.

The 12th century saw another civil war in England as the crown was fought over by Stephen and Mathilda. The Scots openly support Mathilda and use the opportunity to invade Northumberland. Although defeated in 1138 at Northallerton, Scotland was given Northumberland and seized the Bishop of Durham's throne in 1141, leaving Northumberland and Durham effectively under Scottish rule, with the Tees the new border. The remaining years of the century saw further border conflict, with the Scots finally pushed back to the liberty of Tynedale and Berwick surrendered to the English in the 1170s.

In 1183, Hugh Pudsey, Bishop of Durham, carried out the Bolden Bude (book), a survey of the church land in Durham and Northumberland. This includes much of the land missed out in the Domesday survey. When King Richard went on Crusade in 1189, Pudsey was granted

more powers becoming Justiciar of England and Regent of the North, taking the Earldom of Sandberge, which included Teesside and the Earldom of Northumberland and further extending Durham's hold on the North.

Major medieval towns began to emerge in this period, often developing alongside palaces and castles, such as Stockton. Notable medieval towns in the region include Bishop Aukland, Barnard Castle, Billingham, Chester-le-street, Darlington, Guisborough, Yarm, Stockton, Redcar and Hartlepool. Hartlepool and Yarm were also important medieval seaports. Known medieval settlements within the area include earthworks from East House Farm, near Coxhoe; Garmondsway village; Layton village, Thulthorpe village; and Grindon and Trimdon, which contain Norman churches. Other villages such as Cornforth, Tursdale, Ferryhill, Fishburn, Sedgefield and Norton are of likely early medieval origin and many settlements in the region retain elements of Anglo-Saxon or Norse etymology which suggest early medieval origins (Ekwell 1960). The rural landscape comprises small settlements often in the Norman style where rows of farmsteads were separated by a central green. The farms worked individual furlongs and kept a mixed arable and livestock economy.

Mining is recorded in the area from the 12th century, with the Boldon Bude highlighting coal mining at Escomb. Inland sea coal was mined as early as 1298 near Spennymoor. Mining is also suggested as taking place at Coxhoe, Ferryhill and Thrislington. From the 14th century onwards, coal mining became a lucrative trade, using the shipping routes from established sea-ports, particularly the large port at Newcastle. Iron was also mined in Durham attested by a parliamentary petition in 1306 against the Bishop of Durham for felling parts of Weardale forest for charcoal to power the iron bloomeries. Salt was also being created at Hartlepool in the 14th century, though it is unlikely it would have been made as far inland as the study area.

Border disputes continued into the 15th century with raids from Scotland including William Wallace's campaign at the end of the 13th century and Robert Bruce in the 14th century. At various stages, areas including Hartlepool, Swaledale, York, Durham and Newcastle were attacked. The Black Death reaches the North in 1349 and infects many villages already weakened by near constant border warfare. Once again parts of the study area may be wasteland.

Tynedale, to the northwest of the study area had been a liberty since the Norman Conquest, often in Scottish hands and if not outside the law, very much out of sight. The liberty was abolished in 1495 and from that point on the Tynedale clans became a law unto themselves, frequently taking up reiving (rustling); taking livestock and goods from neighbouring land. The constant threat of reiving led to the construction of peel towers, small defendable towers, found in many villages in Northumberland. Whilst County Durham largely avoided the reach of the reivers, they were opportunists and raided Weardale during the 16th century rising of the north when much of the fighting age population was absent.

Three battles were thought during the War of the Roses in Northumberland, but all outside of the immediate study area. By the Tudor period, England held Berwick, with the border firmly established along the Tweed-Esk-Solway. After Flodden Field in 1513, the Scots army was in disarray and in the 1530s the Scottish borders were ravaged by the Earl of Northumberland, destroying castles, churches and towers.

Henry VIII's desire to divorce Catherine of Aragon and cut off the flow of money to Rome brought about the English Reformation, closely followed in the 1530s by dissolution of many monasteries across England including notable houses in the north-east; Hartlepool Greyfriars, Guisborough, Yarm, Finchale Priory, Egglestone Abbey, Durham Cathedral Priory and Whitby Abbey.

In the mid 16th century the northern landowners rebelled against Queen Elizabeth in the rising of the north, and sought to re-establish Catholic rule by allying with the Scots and their imprisoned Queen. The rebellion was put down and executions carried out across villages and towns between Wetherby to Newcastle from 1570 to 1572. It is unknown if any of the

settlements within the study were affected. The northern ports were also hit by plague in the later 16th century, striking Newcastle, Hartlepool, Darlington, Aycliffe and Chester-le-street.

5.8 Post-medieval and modern (17th-20th century AD)

The long standing problem of Border reivers was resolved by King James in the early years of the 17th century when he started deporting troublesome clans to Ireland. Reiving died out with a few years of this harsh measure. From the 1630s onwards the North was subject to plagues and warfare. Plague struck Newcastle again in 1636, killing over 5000 people and leaving the city devastated. It is not known to what extent this reached the outlying communities. By 1640 the Scots invaded and crossed the Tyne, seizing Newcastle and Durham, though the more southerly communities in the study area would have escaped. As the Civil War escalated, the Scots army again crossed the Tyne skirmishing near Sunderland and fighting alongside parliamentarians at Marston Moor before capturing Stockton Castle.

Following Cromwell's victory and the execution of King Charles, Durham and Stockton Castles, once owned by the Bishop of Durham are passed into private hands. Stockton Castle is then destroyed in the mid 1600s. Stockton's fortunes do recover by the 1700s as an agricultural and mineral port, when it gains independent parish status from Norton. Stockton starts shipping coal by the early 17th century and soon overtakes Yarm and Hartlepool as the largest port in the immediate area.

Coal mining, long a commodity in the north-east began to be more extensively mined outside of Tyneside and reached County Durham in the 1800s. From this point on, there was a dramatic increase in the number of mines and settlements sprang up around the mining areas. Spennymoor lay within the coalfields and over 100 pits and drifts were opened in its vicinity in the 19th century. Cornforth, Tursdale and Thinford were also noted for their collieries in this period. Quarrying of sand, gravel, limestone and clay is also known to have taken place near Tursdale, Trimdon, Thorpe Thewles, Cornforth, Fishburn and Coxhoe. Lead mining took place in the wider region, particularly in Weardale and Teesdale.

Outside of the coal measures, the landscape was dominated with agricultural production, with many of old furlong fields finally enclosed under the 17th parliamentary act. The common land around Thorpe Thewles is believed to have been enclosed prior to the act in the 16th century. Earthworks of ridge and furrow agriculture are scattered across the study area and are difficult to accurately date. Some of the fields may well have their origins in the medieval period, though furrows could equally have been formed much later. Wool mills begin to develop in the area, making use of the large local flocks.

Railways revolutionised the north-east in the 19th century at a time when several of the historic ports had faded, with Hartlepool and Yarm declining to no more than fishing villages. This changed with Hartlepool becoming a coal port and ship yard, connected by rail. Other nearby settlements which gained at this time included Middlesbrough, a hamlet with a population of 30 in 1829. After being connected by rail to form a new coal port and later a shipyard, iron and steelworks, the town grows exponentially until by 1900 the population stood at over 90,000.

Two railway lines crossing the study area; the Clarence Railway line was opened in the 1830s, with a section running north through Coxhoe Junction and another past Norton sub-station. In 1844, the North Eastern Railway, York and Berwick Branch from Darlington to Newcastle was opened, with the line passing to the west of Cornforth.

The 19th century also saw an increase in industry across the north-east, fuelled by coal and steel. An alkali works was set-up at Middlesbrough in the mid 19th century using buried rock salt. Salt production was also undertaken in Billingham in the late 19th century, which then became a centre for chemical production in the early 20th century, including producing ammonia, fertilisers and later, plastics.

By the 20th century, the region begins to decline, hitting a nadir in the 1930s with large-scale unemployment and business closures. Although the region recovers post-war, by the late 20th century colliery and ship-yard closures have again caused rising unemployment and towns to shrink. Many of the colliery settlements which expanded in the 1800s begin to shrink back towards their pre-19th century size.

6 Results

Twenty-six access tracks were monitored within County Durham, with eight tracks producing sufficient archaeology to warrant full reporting in Section 6. The most significant of these was Butterwick Road (Access 27), which revealed part of a Romano-British farmstead. Of the other seven access tracks, the majority revealed limited archaeology, typically remnants of medieval ridge and furrow agriculture or relatively recent field boundaries and drains. Eighteen access tracks contained either no or minimal archaeology such as palaeochannels, modern hedgerows, modern tracks and modern drains.

Seven access tracks were monitored across Teesside, with four tracks producing notable archaeology. The most significant of these was Low Middlewood (Access 37), which revealed part of a Romano-British settlement alongside medieval furrows and a large medieval ditch. The other three tracks revealed similar archaeology to those in County Durham, typically medieval ridge and furrow and discrete features. Three access tracks contained no archaeological features at all.

All sites are summarised in Appendix N; those sites containing no or minimal archaeology are tabulated in Appendix O.

6.1 Spennymoor: Access Track 2/ Tower ZXC 60

The access track servicing tower ZXC60 (NGR 429020 534501) was located in the field to the east of the Spennymoor Sub-station and 1.6km to the west of Cornforth (Figs 7 and 13). The entrance utilised an existing, concrete, private road located to the north of Metal Bridge cemetery. This concrete road progressed west for 600 metres where the newly constructed road turned 90º south across a field towards tower ZXC60.

Tower ZXC60 and its track way were located on the edge of a valley, with a slope rising to the north, west and to the east which gradually increases towards Spennymoor. The valley drops to 80m OD to the west of the site where the modern train line runs past.

Background

Remnants of medieval or post-medieval ridge and furrow agriculture have been identified approximately 500m south-west of the Spennymoor sub-station in a programme of geophysical survey and trial trenching undertaken at High Whitworth Farm.

Spennymoor was once part of Whitworth Estate. Whitworth Hall, which lay approximately 5km west of Spennymoor was built in the 12th century and was bought by the Shafto family in the mid 17th century. The Shafto's were prominent politicians and included Robert Shafto, popularly identified as Bobby Shafto in a local folk song during the 18th century. The original manor was demolished in the mid 19th century.

Spennymoor itself was a minor settlement until the 1800s when it was enlarged into a town to cope with the increase in population as part of the Sedgefield colliery work. Since the decline of the coal industry, Spennymoor has been in economic decline.

Metal detection

No artefacts were recovered during the metal-detecting survey of this site.

Site Description

Two 0.3m wide, parallel ditches, **60014** and **60020,** oriented north to south were exposed in legs C and D (Fig 13). Both features were linked by a further two ditches, **60023** and **60025,** which were aligned on a 90 angle forming a northerly aligned ladder pattern of ditches. The northern most extent of ditch **60014**, within leg C, demonstrates what appears to be a sharp 90 turn to the west recorded as **60018** but part of the same ditch system.

Ditch **60014/60018** truncates earlier ditch **60012,** which extended to the east beyond the site dimensions. East west aligned ditch **60003** extends from leg C into leg B and may have been part of the same system as ditch **60014/60018**. Modern, east west aligned drains **60005** and **60022** were also recorded and represent further recent drainage work. An undated circular post hole **60006** was revealed in leg B, though there is no indication how this related to the drainage system in place.

Finally a north-east south-west aligned furrow **60008**/ **60012** was present, crossing both legs B and C and extending beyond the site dimensions. A narrow north-west south-east ditch **60010** crossed the edge of one of the tower bases and probably represents another drainage feature.

Conclusion

A network of ditches and drains were discovered during the monitoring of tower ZXC60. Artefactual dating was limited, but these features appear fairly recent in date presumably representing drainage put in place in the modern era prior to the construction of the nearby sub-station

6.2 Thinford Access Track 3/Towers ZXC58 and ZXC59

Access 3 and towers ZXC59 (NGR 429337 534643) and ZXC58 (NGR 429617 534720) were located 1.3 km to the east of Thinford and 1.5km to the west of Cornforth (Figs 7 and 14). The entrance utilised an already existing concrete private road located to the north of Metal Bridge cemetery. This concrete road progressed west where the newly constructed road turned 90º south across a field towards Cooksons Green and tower ZXC59. The track then turned 90º east and terminated at tower ZXC58.

The Thinford complex of towers and track way was located on an inclining slope which gradually increases towards Spennymoor situated between 105m-108m AOD. The valley drops to 80m AOD to the west of the site where the modern train line runs.

Background

Thinford is a small hamlet of uncertain date of origin located on the former Great North Road. Thinford may be a mutation of Thenford, which would have been derived from the Old English *Thane* Ford, literally ford of the thanes (a servant or retainer). The settlement is known to have existed in the mid 14th century, when a fulling mill was recorded (possibly on the site of the current Thinford Mill). However, the mill was noted as ruined by 1384. Little is recorded regarding the settlement, until the construction of the Thinford Inn (Grade II listed) in the mid 18th century. The settlement presumably existed as a staging post in the post-medieval period with a coaching inn and continued at this size into the modern era. With the

creation of modern road systems, the Great North Road became obsolete and the Inn's and purpose will have disappeared.

A single sherd of Roman pottery (D412) has been previously located just south of Access 3.

Description

During the monitoring of the access track, a series of north to south aligned furrows were discovered (Fig 14). The presence of these furrows suggests a larger medieval or post medieval system of fields and land division existed across the local landscape. Two of these furrows, **030304** and **030404**, were excavated in an attempt to find datable material which may allude to the date of the furrows. Both of these furrows were revealed to be very shallow, measuring only 0.15m in depth by 2m wide (Fig 14).

The excavation of tower bases revealed further evidence of medieval/post-medieval field systems. Leg C in tower ZXC59 revealed an undated furrow, **59005**, and a narrow undated ditch, **59003**, which was aligned perpendicular to the furrow.

The soil shadows left by the remains of tree root systems were also found in leg A of tower ZXC59 and leg A of tower ZXC58.

Conclusion

The presence of furrows and potential remnants of medieval/post-medieval ditches suggest this site may have been under plough for some time, making use of the till soils.

6.3 Cooksons Green Access Track 5/Tower ZXC57

The entrance to access 5 was located off the Metal Bridge to Ferryhill road (Fig 7). Initially advancing east from the main road, the track sharply turned north after approximately 120m. The northern part of the track terminated at tower ZXC57 (NGR 429995 534732).

Cooksons Green access tracks and towers were located between 90m and 100m AOD approximately 1km to the west of Cornforth and 0.1km north of Cooksons Green. The access was sited on a relatively flat field with a steep incline immediately to the east which slumped down to 80m down to the route of the modern train line. The sudden declivity in ground level was a result of the constant modification and clearance for the train track.

Background

Access 5 lies in open farmland near Cooksons Green Farm. An unidentified cropmark lies directly north of the access adjacent to Metal Bridge, a former railway bridge. The route of the North Eastern Railway, York and Berwick Branch from Darlington to Newcastle opened in 1844 and passes directly east of the site. Some land clearance and dumping of waste material may be expected within the vicinity of the rail track.

Metal detection

A Victorian penny was recovered during metal detecting.

Description

The first part of the access track revealed a series of furrows, all of which were broadly aligned north to south. The furrows within this field are part of a series of ridge and furrows

which would have been part of the medieval and post-medieval agricultural landscape. Very subtle remains of ridge and furrow could be seen on the surface of the field during the monitoring. The furrows did not appear to occur at regular intervals suggesting that they mostly been removed by modern agricultural practice. Two of the furrows, **050103** and **050107**, were excavated to confirm there interpretation and attempt to discover some datable material.

A small regular linear arrangement of stones, **050105**, was discovered approximately 10m from the modern road and on the same alignment.

Conclusion

Remnants of ridge and furrow agriculture reflect the pre-industrial land-use in this area, while the remains of a linear stone alignment probably marks the base of a robbed out farm boundary wall.

Pottery and glass were found in a modern dump within the tower foundations of legs A and B. This dumping is probably present due to the ground clearance and levelling prior to construction of the North East Railway train track in the 1840s, directly to the east. A Victorian penny was discovered in the topsoil during the metal detecting survey as well as fragments of mid to late 19th century pottery and glass.

6.4 Cornforth Lane Access Track 13

Access 13 was located on Cornforth Lane immediately east of the A1(M), 1km south of the centre of Coxhoe (NGR).

Metal detection

Two artefacts were recovered from the topsoil (context 130101) during metal detecting. An item of treasure , a sixteenth century cast silver hairpin (FAKL-860142), was found (NGR 431300, 534700), as was an eighteenth century cast copper alloy buckle frame (Appendix G).

6.5 Stobb Cross Lane Access Track 14/Towers ZXC49, ZXC50 and ZXC51

Located 1.5km to the east of Cornforth and 0.5km north of Stobb Cross Lane, the entrance was on the west of the A177 just before a distinct 90º bend near to Coxhoe (Fig 7). The access was located on the 120m contour on a slope with the inclining gradient to the south. The access track progressed north westerly servicing towers ZXC49 (NGR 432713 534634), ZXC50 (NGR 432340 534750) and terminated at tower ZXC51 (NGR 431946 534855) next to the A1.

Background

Stobb Cross Lane lies near the route of Cade's Roman Road (named after an 18th century antiquarian), which passes to the east of the site and once ran from Brough-on-Humber to Newcastle and the eastern end of Hadrian's Wall (D3182).

Undated circular cropmarks (D8017) have been noted just west of the A1 and to the north of the site. Other undated cropmarks have been noted near Coxhoe (D2732, D2735). A possible earthwork enclosure has been noted south of the site (D1122), while part of the course of Coxhoe Beck has also been picked up on nearby cropmarks (D8009). Two World War Two pill boxes are also located near Coxhoe Bridge, just north of Stobb Cross Lane.

Nearby find-spots include a Bronze Axe (D5631) and medieval pottery (D3181).

Metal detection

A selection of 18th, 19th and 20th century artefacts was recovered during metal-detecting including a D.L and Co. Ltd colliery tally. This tally belonged to Dorman Long and Co Ltd, who owned nearby Tursdale Colliery from 1923-1947 (Durham Mining Museum 2011- accessed 19th December 2011).

Also recovered, were two Victorian pennies, a George I farthing, lead metalworking waste and lead casting waste. Thirteen fragments of late 18th to mid 19th century clay pipe were also found in topsoil, suggesting casual discard or accidental loss of personal objects in the field.

Description

A series of furrows which are the remains of the medieval/post medieval agricultural landscape were broadly aligned north to south and located intermittently along the route of the access track. Three of the furrows **140904**, **140906** and **140908** were excavated to prove the interpretation of the furrows and also attempt to retrieve some datable material. A single sherd of medieval pottery was recovered from one of these furrows (Appendix C). An upstanding ridge **140303**/**140304** was found next to an extant hedge line which is on the same alignment as the furrows. A spread of north-south aligned cobbles was discovered below the topsoil next to a modern public right of way. These cobbles probably represent a former track or footpath in the same place as the modern right of way.

An undated ditch **140902** was discovered underneath furrow **140904,** and is potentially of pre-medieval date.

Conclusion

The monitoring of Access 14 was expected to reveal background levels of archaeology due to the proximity of the Roman Road, abundance of cropmarks and several independent find spots. However, archaeological evidence was restricted to an undated ditch of probable pre-medieval date and a series of medieval-post-medieval furrows, such as have been noted across the project. This suggests that despite the presence of a nearby Roman Road, the majority of cropmarks nearby are likely further remnants of ridge and furrow field systems or part of Coxhoe Beck.

The presence of a tally from Tursdale Colliery adds to the social history revealed in this project.

6.6 Catley Hill Farm Access Track 19 and Towers ZXC39 and 4TF38C

Access 19 was located 0.5km to the west of Trimdon and 0.2km to the north-east of Catley Hill Farm (Figs 8 and 15). The entrance to access 19 was to the south of West Lane and was aligned north to south. The track serviced towers ZXC39 (NGR 435680 534022) and 4TF38C (NGR 435686 534026). The access and towers were on a fairly even plateau close to the top of a ridge of a prominent hill. Approximately 50m to the south the land begins to drop away and form a steep hill.

Background

The cropmark of a possible prehistoric ring ditch lies near Catley Hill (D1091), and the cropmark of a possible Iron Age enclosure is noted at nearby Harap Hill (D377). Undated crop marks are also known near Trimdon (D2800 and D3252).

Trimdon (Old English for wooden cross/monument on hill) and Catley (Old English for wild-cat wood or clearing) Hill probably both has their origins in the early medieval period. Trimdon's parish church was founded in the Norman period adjacent to a narrow village green and two rows of houses, typical of the Norman period settlements in this area.

Metal detection

A 19th century bronze eyelet was recovered during metal-detecting. Three flints and two pieces of Romano-British pottery were also recovered during site stripping

Description

A series of furrows of possible medieval or post-medieval date, were revealed in the access and tower working areas (Fig 15). One of the furrows **190104** was excavated and recorded to confirm the interpretation.

Furrow **64005** located in one of the foundations for tower 4TF38C, was removed and revealed an earlier, though undated, pit **64006,** which cut an earlier post hole **64015**. Another furrow **39002** was revealed in tower foundation D in ZXC39. This furrow was removed with the mechanical excavator but did not reveal any further features.

Conclusion

The remains of a series of furrows were revealed, likely dating to the medieval or early post-medieval period and possible related to the nearby medieval settlement of Trimdon. An earlier undated pit and posthole were also recorded though no finds were recovered and the fills were sterile.

6.7 Trimdon Access Track 21/Towers ZXC36 ZXC37 ZXC38 4TF38B 4TF38T 4TF38A

The Trimdon access was a large complex system of tracks and towers starting to the south of West Lane just on the western periphery of the village of Trimdon (Fig 8). The access track initially progressed south from West Lane and then angled to the south-east. The access track was on a steep gradient which was at 170m OD at the entrance and terminated at 130m OD. A series of small access tracks were aligned east to west off the main access to service other towers. The access track included tower ZXC36 (NGR 436355 533413) which was originally planned to be serviced by obsolete access 22.

Background

This access again lay close to the medieval settlement of Trimdon and its associated undated cropmarks (D2800 and D3252). Further remnants of medieval and post-medieval furrows as seen at Catley Hill were expected.

Metal detection

A 19th-20th century copper half-penny, 19th-20th century bronze buckle and an undated bronze stud were recovered during metal-detecting.

Description

A series of north-south aligned furrows were revealed during the removal of the topsoil prior to the establishment of the stone roads. One of these furrows **67004** was excavated to confirm the interpretation.

East -west aligned ditch **67002** was positioned near the furrows, though no artefacts were recovered to date the feature.

Conclusion

As with Catley Hill, the remains of a series of furrows were revealed, likely dating to the medieval or early post-medieval period and probably related to the nearby medieval settlement of Trimdon. An undated ditch was also present.

6.8 Butterwick Road Access Track 27/Towers ZXC27 ZXC28 ZXC29

Access 27 was 0.5km to the west of Bridge House, 1.5 km north-west of Butterwick. The entrance to the Butterwick road complex of towers and access was west of Three Horse Shoes Inn on the Butterwick Road (Figs 9 and 16). The access track progressed south east south and then turned 45º to the south west south where it terminated at tower ZXC27 (NGR 437391 530727) just before the river Skerne. Two further access tracks were aligned east to west and were connected to the main part of the track approximately after a third of and again at 2 thirds along the access track. Both of these serviced towers ZXC29 (NGR 437323 531423) and ZXC28 (NGR 437352 531084). The majority of the access track was on the 100 metre contour, with the centre of the access track declining 10 metres down to the route of the river Skerne.

Background

Butterwick Road lies just southeast of Fishburn, a medieval settlement first noted as *Fisseburne*. The settlement was probably named from the Old English *Fish Burn* (A Scots and Northumbrian word for stream-possibly derived from the Saxon *brunna*) and is located on a small limestone hill just north of the River Skerne, which may have been the aforementioned burn. Fishburn is recorded from at least the 11th century, owned by the Fissebourne family, their name presumably taken from the village.

This small agricultural settlement expanded in the 19th and early twentieth century with the expansion in mining across the north-east but has diminished along with many villages since the colliery closures of the late 20th century.

An 1839 tithe plan records a field named Skeleton Hill lying just east of Butterwick Road and southeast of Fishburn. This may indicate the presence of a pre-19th century graveyard, which given its location away from settlements would suggest a medieval or earlier date. Possible brick making is also highlighted by the tithe map, with Hollow Field, Brick Kiln Field and Brick Field all recorded near Mill House.

Undated earthworks (D 1096 and D 1097) are also noted lying between Access 27 and Butterwick Road itself.

Metal detection

Metal-detecting recovered nine bronze and iron objects dating from the 19th-20th century.

Description

Butterwick Road contains Roman deposits located along the north-south aligned part of the access track just south of Mill House (Fig 16). These remains included a partial ring ditch **0071/0074**, which was adjacent and outside of a larger ring ditch **0051/0065/0055** (Plate 3) and probably represents at least two phases of house construction. The larger ring ditch included three discrete and undated pits **0070**, **0072** and **0056**, which may have represented internal features. A third, curving ditch **0061**, truncated the upper fill of ring ditch **0051/0065/0055** and may represent a third phase of construction.

Further north along this length of track were located two more curving ditches **0059** and **0047**, both of which appeared heavily truncated. Ditch **0047** did however produce part of a Roman glass bangle (Appendix G; Fig 27 h)) alongside Roman pot sherds (Fig 27 a) and d)) and animal bone suggesting primary settlement deposition.

Four medieval or post-medieval furrows, aligned east-west, were located at different points along the track, including truncating ditch **0059** and furrow **050**, which truncated ring ditch **0051/0065/0055**.

A possible stone trackway **044** (Plate 4) was noted north of Roman ditch **0047**; however, the track was in poor condition with only a fairly small area of compacted stones surviving.

Conclusion

Roman remains were revealed in part of the access track, including what appeared to be fragments of several phases of ring ditches. With the limits of the track access preventing the full width of features being revealed and no known cropmarks or geophysical data for this site it is difficult to estimate the size of the settlement. However, the relative paucity of finds (glass bangle apart) suggests this is likely of Romano-British farmstead size, rather than a major community. Such farmsteads were typically fairly self-sufficient trading surplus produce between nearby farms and local markets.

Cades Road lies a few kilometres to the west, and would perhaps have been the nearest access to larger markets such as the settlements at Lanchester and Binchester though it is doubtful these would have been regularly accessed.

Fragments of ridge and furrow were noted at several points on the track and probably relate to medieval agricultural systems from farms attached to nearby Fishburn. The possible trackway remnant is of uncertain date and could represent part of a fairly recent farm track.

6.9 East Close Access Track 31/Towers ZXC22 ZXC21 ZXC20 ZXC19

Access 31 was positioned to the south of A689, 0.5km to the east of Cote Nook Farm 0.5km to the west of East Close and c.3km southwest of the Butterwick (between NGR 437613 528883 and NGR 437883 527920) (Figs 10 and 17). The access was initially aligned to the south east where it turned 135º to the west where it connected with a north to south aligned part of the access track. The East Close access was on slope gradually declining to the south.

Background

The nearest settlement to East Close is the shrunken village of Butterwick, lying c.3km to the northeast. Butterwick was an early medieval settlement, recorded in the 12th century as *Boterwyck* (Old English for butter or dairy farm). The farmsteads of East, West and South

Butterwick mark the extent of the village; the historic core has long been abandoned and can be seen as an earthwork.

Nearer Access 31, the farm of Cote Nook may also have medieval origins based on its place name etymology, showing a mix of Old English and Scots. *Cote* is from the Old English for cottage or hut and *Nook* is probably a modern translation of *neuk*, Scots dialect for corner or remote, literally being the remote cottage or hut. Nearby East Close farm is likely of more recent origin.

Field name evidence from just south of Cote Nook Farm suggests a possible post-medieval or early modern pottery kiln once existed in the vicinity. East Potters Close and West Potters Close are recorded on the 1838 Sedgefield tithe map just to the south of Cote Nook Farm. Brick Hill Field is also marked on the same map between East Close and Cowley House Farm.

Metal detection

An 18th century bronze button, an undated iron handle, a 17th-20th century lead pump valve weight and two 19th-20th century half-pennies were recovered during metal-detecting.

Description

Two east to west aligned relict tracks **310206**, **310405** comprising firm sandy clay and sub rounded cobbles were located during the monitoring of an access track and the tower working area for tower ZXC21. These tracks probably relate to post-medieval or early modern tracks laid down for farm access. A pit, **310204** just south of the A689 was excavated and revealed the base of an Iron Age-Roman pot (Appendix B, Plate 5). The pit, 0.15m in diameter, demonstrated a high level of truncation due to ensuing years of agricultural practice since the deposition of the pot.

Conclusion

The most significant feature at East Close was a pit containing the truncated remains of a native tradition pot, of a type which spans the later Iron Age and Roman period. The high levels of truncation at this point may suggest further remains were once present, but have since been removed by agriculture.

6.10 Layton Access Track 35/ Towers ZXC14 ZXC15 ZXC16 ZXC17 ZXC18 4TF14R 4TF15R

The access was located 0.3km to the west of Cowley House Farm and 1km south east of Cote Nook Farm (Fig 11). The visible remains of the deserted medieval Manor of Layton can be seen opposite the entrance to the access. Much of the access track for access 35 and the associated towers was on a pre-existing track way which provided access for Cowley House Farm and Long Plantations (between NGR 439268 526649 and NGR 438133 527622). The landscape immediately around the access tracks and the towers was dominated by rolling drumlins.

Background

A flint scatter (T2871) has previously been recorded adjacent to Access 36 and to the east near Brierley Wood, while the cropmark of a possible prehistoric enclosure has been noted near Thorpe Larches (T1460).

Medieval archaeological remains are known from the immediate area. The earthworks for the former medieval Manor of Layton (D 354/SM32731DMV) are visible just west of Access 35. Earthworks suggest the Manor once possessed buildings, fishponds, enclosures, field systems and a hollow way. Layton's place name derives from the Old English for farmstead on a stream.

To the south-east of Layton, the remnants of a medieval field system are visible near Thorpe Larches (T1477). Thorpe Larches was likely a Danish settlement, with *Thorpe* coming from the Old Danish *thorp* for a small village or farmstead tied to a larger settlement; 'Larches' is presumably a later addition referring to local woodland.

Cowley House Farm to the immediate north-east also retains remnants of ridge and furrow visible on aerial photographs. The suffix place name Cowley is probably a derivation of Old English *leah* for clearing or wood, though the first part of the name is less certain and could come from anyone of a number of translations including; *cofa* (cave or recess in a hill) and *col* (charcoal burning).

Metal detection

Metal-detecting recovered a 17th-19th century lead gunshot, an undated lead weight, an undated lead spillage, a 19th-20th century lead bag seal, a 19th century penny and a 19th-20th century whetstone. A single worked flint was also recovered.

Description

During the topsoil stripping a series of furrows cut into drift geology were revealed. These furrows are the partial remains of a larger system of ridge and furrow which would have been part of the medieval agricultural landscape. Some of these furrows **350203**, **350206** were excavated to confirm there interpretation and attempt to locate some datable material, with medieval sherds recovered from site.

Conclusion

Remnants of ridge and furrow probably relating to that seen at Cowley House Farm were recorded. The apparent abundance of remnant medieval field systems and settlements in the immediate area suggest this part of the route may have been fairly densely utilised in the medieval period. However, it is apparent that much of the medieval landscape was subsequently abandoned for some time with the resulting good levels of preservation, which perhaps indicates this is one of the areas of Teesside deserted during the turbulent later medieval period.

6.11 Low Middlewood Access Track 37/Towers ZXC3A ZXC4A ZXC5A ZXC6A

The entrance to access 37 was next to Low Middlewood Farm and 1.2km east of Thorpe Thewles. The access track ran north to south on a relatively flat part of the landscape at 30 metres OD (between NGR 441439 523212 and NGR 441229 524247) (Figs 12 and 18). The final 100 metres of the access track which serviced ZXC6A suddenly drops to 15m AOD at a water course.

Background

The Romano-British site of Thorpe Thewles lies c.3km to the west of Low Middlewood and contains the remains of a well-preserved enclosed settlement of roundhouses and associated fields, spanning the later Iron Age to early Roman period.

Thorpe Thewles, like Thorpe Larches is likely a Danish settlement tied to a larger settlement. The suffix Thewles is probably derived from the Old English *theawleas* meaning immoral. Quite why the settlement was considered immoral is not recorded.

Remnants of medieval field systems are recorded between Thorpe Thewles and Low Middlewood (T 699) and may be expected to encroach onto the access track.

Low Middlewood lies just to the east of the ruins of Blakeston Hall (T821), a medieval manor. Settlement at Blakeston is recorded from at least the 11th century, when clergy from Durham occupied the Manor at *Bleikestuna,* the place-name probably derived from the Old Norse *Bleikr* (Pale) and Old English *Tun* (farm or village), which suggests a pre-conquest date for the settlements origins. The Manor was rented out in the 13th century and the first of the de Blaykeston family soon arrived as chaplain. By the 14th century this family had successfully bought out the Manor and other land in the region. During the 16th century the family name had evolved to Blakiston; the hall, now known as Blakeston, and its associated grounds is a ruin visible on aerial photographs.

Metal detection

Metal-detecting recovered a 17th-18th century bronze buckle, two undated lead weight, three undated lead spillages, a lead off-cut, a 19th-20th century lead bag seal, an undated bronze off-cut, two 19th-20th century bronze rivets, a 19th century sixpence, a 19th century halfpenny, and an undated iron blade.

Description

Low Middlewood contains remains of both Romano-British and medieval date, all within the immediate area of Tower 5A (Figs 12, 18 and 19). The term Romano-British is taken in this context to describe remains which could span the later part of the Iron Age through the Roman period. As little pottery was recovered, and much was in poorly dateable native tradition fabrics, no attempt at has been made at refining the site phasing beyond these broad periods.

Romano-British

This site includes several partial ring-ditches, including **0107**, located in the western side of the site with an entrance to the east and an estimated diameter of 8m. This ditch was truncated by a larger north-west by south-east aligned ditch **0110**, which extended beyond the site dimensions.

Directly outside of ring ditch **107** (Plate 7), was located a possible furnace or field oven, comprising a clay-lined pit **0111**, and possible flue or rake out features **0116, 0118** and **0114** (Plate 6). Very little slag was recovered from this site (three pieces and none from the vicinity of these features), which may indicate this is more likely an oven, possibly utilised for communal bread making. Identification of the function of this feature was hampered because of heavy truncation as a result of later agricultural practices.

Another ring ditch **0098** was located in the eastern part of the site and had an estimated internal diameter of 8m and an east facing entrance. This ditch was truncated by a curving feature **05038**, which was re-cut itself by ditch **0100**.

Neither of these curving features appears to be a ring ditch and is more likely part of a small curving boundary which terminates opposite an east-west aligned ditch **05035/05025/05023/05021**, forming a probable entranceway c2.5m wide.

North-west by south-east aligned ditch **0045/05012** was aligned perpendicular to ditch **05035/05025/05023/05021**, terminating 1m away from its northern margin. These ditches appear to represent part of a field system, which overlay an earlier and similar arranged layout of ditches, aligned approximately northwest by southeast.

The earlier field layout is marked on the west by ditch **0019/05016/05014**, which lies parallel to ditch **0045/05012** (Plate 8). A discrete pit **0042** lies between the two ditches; however no artefactual dating was recovered from its fills.

The eastern side of the field was formed from north-west by south-east ditch **0016/05045**, which terminates c.2m beyond and is truncated by ditch **05035/05025/05023/05021**. The southern side of this suggested field is formed from ditch **05043**, which terminates adjacent to ditch **0016/05045** and extends west before being truncated by ditch **05035/05025/05023/05021**

Within the southern margin of the site are located several more Romano-British features. A large north-west by south-east aligned ditch **0096/0094** extends from the south-east corner of the site before terminating. It is uncertain what this ditch could relate to, however connected features may lie beyond the area of investigation.

Towards the south-west corner of the site, a narrow curving ditch **0040**, which extended to the north before terminating, was revealed. This ditch lay on the western side of a slightly larger ditch **0032** on a similar alignment. Ditch **0032,** was then truncated by a 1.5m wide ditch **05007/0031**, which probably marked a second phase of boundary creation. This ditch extended to the north into the unexplored central area of site, but does not appear to continue through to the areas stripped in the north. The terminal of another ditch **0035** was recorded truncating ditch **05007/0031**; however it is uncertain what period this feature belongs too.

Two large areas of spread subsoil (05017) containing occasional Romano-British finds were present near the northern part of the site. Given the number of furrows also in this area, it is likely this represents a build-up of ploughed out Romano-British material from abandoned and likely buried, features during the medieval period.

Medieval

Several medieval furrows were recorded on site; all aligned approximately north-south and were only recorded on the northern half of the site. These furrows included features **0122, 0018/05003/05019, 0017** and **0105**. A large north-east by south-west ditch **0023/0025** containing medieval and Roman pottery (Fig 27 e)) extended across the south-east corner of the site and potentially represents a previously unrecorded medieval boundary. At its widest point, this ditch measured over 4m wide; however, after careful cleaning it was resolved that the upper fill had been artificially spread by ploughing and the true width was closer to 2.5m wide by 0.48m deep.

Undated

Several linear features were present on site, which do not easily fall into either of the previously described phases. There is a reasonable probability that these are all of recent date.

North-south ditch **0120** truncated ring ditch **0107** at the northwest corner of the site and resembles a recent, though undated, drainage feature.

Two narrow, north-south aligned, parallel ditches **0011** and **0007** were located in the north-east corner of the site, neither contained any dating material and both were cut from just below the topsoil, suggesting these may be fairly recent.

A discrete, shallow, irregular feature **0104** truncated the upper fill of Romano-British ditch **0100/05036** and probably represents part of an animal burrow.

Conclusion

The fragments of at least two phases of Romano-British field systems and associated ring ditches were revealed in excavations at Low Middlewood. Neither phase produced high levels of artefacts suggesting these features were either on the periphery of a larger settlement or this represents a fairly modest farmstead. Many of the features extend beyond the excavated areas and further archaeological remains will almost certainly exist in the immediate area.

Environmental evidence (Appendix L) suggests that deposits may have lain exposed to the elements for some time rather than been rapidly buried, which may indicate periods of abandonment, certainly there is limited evidence for recleaning/cutting the apparent field system ditches which might be expected.

The presence of several ring ditch fragments and a probable bread oven suggests habitation certainly took place onsite adjacent to the probable field systems, likely as a farmstead sized settlement rather than a larger village. Environmental evidence suggests hearth sweepings including burnt bone fragments were included in feature fills, which would be typical of burnt food waste being disposed of. The level of truncation suggested by spreads of apparent ploughed out subsoil in the northern part of the site suggests any middens have been removed by later agriculture.

A large medieval ditch against the southern edge of the site suggests an old field boundary, with the furrows lying to the north marking the remnants of ridge and furrow agriculture. These furrows lie only a few hundred metres east of known ridge and furrow crop marks (T 699) and probably once formed part of the outlying fields associated with Blakiston Manor.

7 Discussion

7.1 General discussion

The absence of prehistoric remains beyond find spots of worked flint is perhaps not surprising given these are the most common evidence of prehistoric human activity, and the acknowledged paucity of known prehistoric remains between the River Tyne and Tees. This has been exasperated by the exploitation of the coalfields and coastlines in the 19th century, which will have removed much of the evidence of settlement within these zones.

Romano-British and medieval remains were present, although medieval remains were largely restricted to fragments of field systems, and typically close by known medieval settlements. There were, however, no archaeological remains or find spots dating to the period between the end of Roman occupation and the late medieval period (11th century onwards), with dated finds starting to appear by the 13th century. The apparent absence of any early medieval artefacts or remains is intriguing, and while sites from this period are historically rarer, a tentative connection to the wide-scale uninhabited landscape following the centuries of border conflict and Norman Harrying of the North can perhaps be made.

Post-medieval and modern remains were largely restricted to remnants of abandoned farm tracks, ditches, dug out hedgerows and drainage features. The majority of the metal-detected finds date from this period, which covers the remarkable increase in population density and land-use in the late 18th – early 20th century when the North-East of England became a major industrial power and small settlements became large towns within a few decades, such as at nearby Middlesbrough. The current landscape crossed by the route is largely agriculturally based, with settlements deliberately avoided, which will have limited the impact on post-medieval and earlier remains to some extent.

7.2 Results of potential impacts

Eight potential sites were highlighted in the Environmental Statement and WSI based on known find spots, cropmarks or other data (Table 7.1).

Cornforth (Access 11) contained a circular cropmark of unknown date; upon investigation this was revealed to be part of the backfilled Coxhoe Beck. This same Beck passed through Cornforth Lane (Access 13); there was no evidence of deposits related to a mill.

Stobb Cross Lane (Access 14) passed near a Roman Road and part of a disused railway line, indicating both Roman and early Modern remains may have been present. The site revealed medieval ridge and furrow and a scatter of 19th and 20th century artefacts, recovered from topsoil.

Butterwick Road (Access 27) contained an unknown and undated earthwork; excavation suggests this may be related to the Romano-British features revealed on site.

Three possible sites were proposed for Grindon (Access 36); however no artefacts or archaeological remains were revealed during monitoring. This suggests the medieval field systems note in the area either do not extend across the route of the track, or have been ploughed out. There was no evidence for any activity associated with quarrying or limekilns within the site.

Access	Site Name	Known Archaeology	Date	Results
11	Cornforth	Circular cropmark	unknown	Remnants of Coxhoe Beck
13	Cornforth Lane	Mill	Postmed/Modern	Remnants of Coxhoe Beck
14	Stobb Cross Lane	Roman Road	Roman	No evidence
14	Stobb Cross Lane	Railway	Modern	19th and 20th century findspots
27	Butterwick Road	Unclassified earthwork	unknown	Roman ditches
36	Grindon	Field system	Medieval	No evidence
36	Grindon	Flint findspot	Prehistoric	No evidence
36	Grindon	Limekiln and quarry	Postmed/Modern	No evidence

Table 7.1 Results of potential impacts

7.3 Roman period discussion (Fig 28)

The two Romano-British sites revealed during the project lie within a few kilometres of each other, one in southern County Durham, the other in Teesside. Both appear to represent fairly small rural settlements, likely no more than large farmsteads with perhaps two distinct phases of land-use. Each site also suffers from limited artefactual dating, which appears to show occupation from at least the 2nd to 4th century with some native tradition wares which could conceivably be later Iron Age or Roman mixed in the assemblage. This contrasts with the nearest well-published site of Thorpe Thewles, which spans the late Iron Age to 1st century AD, but lacks a significant later Roman occupation (Heslop 1987). This perhaps indicates the creation of newly cultivated land and newly founded farms following the conquest by Agricola. It is notable that the sites of Low Middlewood and Butterwick Road appear to be in

use after Thorpe Thewles (which lies a few kilometres away) has been abandoned. Roman control of the region may have also encouraged settlement of land by army veterans being rewarded with parcels of farmland for years of service.

Roman material culture influence at the two sites appears fairly limited. Pottery recovered tends towards the native tradition, though there are a few sherds of Crambeck Ware and a scrap of Samian. This is however typical of sites in the North-East, particularly rural settlements (Wright 2007). The fragment of glass bangle at Butterwick Road may also suggest access to wider markets and further remains will undoubtedly lie beyond the dimensions of the excavated sites, which could have contained more in the way of status or imported goods.

A lack of Roman finds within rural sites does not necessarily mean a lack of Roman influence or a lack of social status; feasting, possession of status livestock (including breeding animals) and ceremonial observance can all reflect status and are largely invisible in the archaeological record (Mattingly 2006).

Both of these sites appear to have been abandoned sometime in the 4th century, with no evidence of continued occupation into the early medieval period. There is no evidence of destruction (such as burnt structures) or environmental disaster, which perhaps suggests either the farms yields were simply dropping or markets no longer existed to cater for. The abandonment of Roman fortifications in the region and exodus of soldiers (and likely loss of the wider empire's markets) would have had a profound impact on rural settlements. Rome absorbed much of Britain's grain and woollen goods in the 3rd and 4th centuries, much of which went to the military campaigns. Without this market, many farms may have suddenly had their consumer base collapse and have been forced to take drastic measures to survive. This may have meant turning to subsistence only farming, catering for dwindling local markets or moving to areas with a larger consumer base and greater protection from neighbouring tribes no longer held in check by the threat from Rome.

Angle settlers passed north of the Humber in the 5th century and by the 5th-6th century nearby Norton contained an Anglo-Saxon community; however by this point both farms had been abandoned and were not re-cultivated until the medieval period.

7.4 Later medieval period discussion

Later medieval (Post 11th century AD) remains along the route are mostly restricted to fragments of ridge and furrow agriculture. This is not surprising as the route passes many settlements either known, or suspected, on place name evidence, of having been settled in this period, including Trimdon, Cornforth, Fishburn, Norton, and the probable Danish settlements of Thorpe Larches and Thorpe Thewles. Several abandoned or shrunken medieval settlements are also known from within the area, such as Garmondsway (Plate 2), Layton, Grindon, and Blakeston (Blakiston).

Whilst there appears to be no evidence for early medieval land-use in the area, there is an expansion in settlement and agriculture from the later medieval period onwards, with the earliest artefacts dating from the 12th and 13th century. The lack of earlier material and land-use could be due to a number of factors, though the threat of an unsettled north with border threats from Scots, Danes and Anglo-Saxon raids throughout this period may have limited the number of settlements. The northern rebellion against King William and subsequent Harrying of the North has to also be considered a factor. Rural settlement prior to the 12th to 13th century in this area may have been sporadic and restricted to more fertile or better defended parts of the region, with the widespread abandonment of rural areas during the late 12th century leaving the area through which the route passes without much in the way of cultivated land.

From the 13th century onwards, a more stable North, aided by the growing power of the Bishops of Durham, would have encouraged settlement and cultivation to feed the monasteries and growing towns, particularly when the wool trade became so profitable.

Ridge and furrow developed due to fixed blade ploughs working in straight lines, often with individual families taking a strip of an open, commonly held field. Open fields began to disappear in the later medieval period, with enclosed fields becoming common by the 16th century. Changing ownership of Manors could also influence the survival of early open field systems, as well as the rise of sheep grazing, encouraged by the value of wool, which required enclosed fields. Sir Thomas More, writing in the early 16th century, claimed that sheep were devouring men and towns as avaricious clergymen forcibly enclosed open pasture and displaced traditional farmers so as to graze their sheep.

The investigations revealed little further evidence for agriculture, other than relatively modern boundaries, drainage features, and manure scatters, dating to the 19th and 20th centuries. Ridge and furrow can date into the post-medieval period, as plough technology improved dramatically in the early modern era; particularly with the advent of mechanised ploughing, allowing exploitation of previously difficult to work fields. The enclosure acts of 18th and 19th century parliaments also formalised much of the remaining commonly held fields, ending any still active ridge and furrow fields.

7.5 Effectiveness of the metal detecting survey

Metal-detecting was undertaken in accordance with an agreed scheme (Network Archaeology 2010). Principally this encompassed:

- Scanning access tracks prior to and after topsoil stripping, and associated spoil heaps;
- Scanning working areas of the tower bases prior to and after topsoil stripping, and associated spoil heaps

All metal-detecting was undertaken by an experienced field archaeologist, also skilled in the use of metal-detecting and proficient with use of hand-held GPS equipment. Finds were individually logged and recorded. At the reporting stage, the assemblage was studied by a specialist with a proven record both with metal artefacts and with a background of working with metal-detected assemblages from the Portable Antiquities Scheme (PAS).

One hundred and twenty-five artefacts were recovered and are reported on in Appendix G. Each item's location was spatially recorded with hand-held GPS equipment to an accuracy of c.5m. While heavily biased towards the 19th and 20th century, some notable earlier finds included two Roman finds (a 4th century coin and a glass bangle) and three medieval finds (an Edward I silver penny, a lead spindle whorl, and a 16th century silver hairpin). The remaining finds date from more recent history and are dominated by domestic items, agricultural parts and occasional small coinage and tokens.

As a technique, metal-detecting is relatively low-cost, non-destructive and where accurately spatially recorded, can provide important data towards manuring patterns, casual loss and material culture studies (English Heritage 2006). For the Spennymoor to Norton project, metal-detecting also provided valuable artefactual information from sites which contained no visible archaeological features; this is particularly useful for sites in a modern agricultural landscape which may have suffered appreciable plough damage but retain artefacts within the ploughsoil.

The project produced a limited number of finds, mostly due to a low number of cut features across the route. However, it is notable that metal-detected finds account for 12% of the total artefacts collected, highlighting how valuable this element of the project methodology was in retrieving dateable information.

8 Conclusion

An archaeological scheme of work, including strip and record, a watching brief and limited excavation was undertaken by Network Archaeology on behalf of MWH (UK Ltd) during upgrading and replacement of the electricity network between Spennymoor in County Durham and Norton on Teesside. The programme allowed for the rapid recording of limited archaeological remains, whilst more significant remains could be located by GPS, preserved under a protective membrane and returned to fully record at an appropriate time.

The most significant archaeology recorded comprised two small, Romano-British rural farmsteads, revealed at Butterwick Road (Access 27) near Fishburn in southern County Durham and at Low Middlewood (Access 37) near Thorpe Thewles on Teesside. A single, heavily truncated, Roman pit was also recorded at East Close (Access 35) near Thorpe Larches on Teesside.

Remnants of medieval ridge and furrow agriculture were noted at several points, particularly near the deserted and shrunken medieval settlements along the route such as near Layton on Teesside and near the ruined medieval Manor of Blakiston Hall.

It is noticeable that stretches of the route appear devoid of both archaeological features and metal-detected finds, particularly between Coxhoe and Trimdon where the route crosses open farmland. This perhaps indicates that parts of the landscape have remained relatively uninhabited until the population increase in the 19th century due to mining and improved access with the introduction of rail lines.

Systematic metal-detecting was undertaken throughout the project and recovered a moderate collection of mixed metalwork, strongly biased towards agricultural and domestic 19th and 20th century objects. However, several notable finds were also recovered from metal-detecting including a 16th century silver hairpin at Cornforth Lane (Access 13) in County Durham, a 4th century Roman coin from Trimdon (Access 22) in County Durham, an Edward I silver penny at Carlton (Access 40) on Teesside and a medieval lead spindle whorl at Norton (Access 41) on Teesside. Without metal-detecting these objects are unlikely to have been recovered and many of the apparent blank areas investigated along the route would have provided no further archaeological information beyond the apparent absence of cut features.

8.1 Summary of Recommendations

No recommendations for further analysis work have been made following initial assessment of the archive by the appointed finds specialists.

Recommendations were made for the illustration of selected sherds of Roman pottery and registered finds, all of which have been included in this client report (Fig 27).

Provision for long term storage of all ceramics, worked flint, registered finds, animal bone and clay tobacco pipes have been made, but the stone and production waste assemblages can be discarded because they no longer hold any potential for further work. It has also been recommended that the glass items be passed to suitable teaching collections or discarded.

Particular mention should been made of the fragment of Roman glass bangle and the medieval lead spindle whorl in any subsequent publication that arises from this project, although all assessed material shall be recognised.

9 Archive

The documentary archive comprises:

- A copy of this report
- Relevant and non-confidential documents and correspondence relating to the site held by Network Archaeology

- Finds catalogues and reports
- Site records, as detailed in Table 9.1 below:

Item	Count
Context registers	15
Context sheets	782
Drawing registers	7
Drawing sheets	62
Photographic registers	49
Metal-detector index sheets	7
Sample registers	1
Sample sheets	10
Black and white photographs	840
Colour slide photographs	840
Digital colour photographs	737

Table 9.1 Quantification of the site archive

On completion of the reporting stages of the project, the archive will be prepared for long-term storage, to a standard from which post-excavation assessment could proceed and in a format agreed in advance with the relevant local depository. This will be in accordance with guidelines prepared by the UK Institute of Conservation (Walker 1990) and the Museums & Galleries Commission (MGC 1992). The project archive will be managed in accordance with current guidelines (Ferguson & Murray 1997).

The recipient museums are the Bowes Museum in County Durham and Tees Archaeology respectively.

The recipient museum will receive the document archive, and with the permission of the landowners, any finds generated from the archaeological works.

Prior to the deposition of the archive, the necessary arrangements will be made with the site owners regarding the transfer of ownership of any archaeological finds to the recipient museums. In the event that deposition of the archive cannot be concluded, Network Archaeology will store the archive to a suitable standard until deposition can be arranged. In this event, Network Archaeology will retain ownership of the document archive until the document archive and its ownership is passed to the recipient museums

10 Acknowledgements

Network Archaeology Ltd would like to thank the following for their contribution to the project:

Name	Position	Organisation
Caroline Wynne	Environmental Project Manager/Principal Environmental Scientist	MWH (UK Ltd)
Janet	Principal	MWH (UK Ltd)

Appendix B The Iron Age and Roman pottery

by A. T. Croom and R. McBride

Introduction

The project produced 128 sherds of Iron Age and Roman pottery, weighing 1.494kg, from 5 different sites.

Methodology

The assemblage was sorted into fabric types, and counts and weights per context recorded in an excel spreadsheet noting any form elements present.

Fabrics

Local traditional ware (LTW)
The vessels are likely to have been made locally, but the range of fabrics is typical of those used throughout the whole of the north-east; there are close similarities with fabrics found on Iron Age settlements in Northumberland, such as Pegswood Moor, Morpeth (Willis 2009, 44). The pottery continued to be made into the Roman period without any major typological changes, and so cannot be dated closely.

Fabric 1: dolerite tempering
Soft, hand-made dark grey fabric with angular fragments of dolerite up to 12mm in size

Fabric 2: granitic tempering
Hard, rough fabric with abundant inclusions (up to 6mm in size) of angular quartz, feldspar and mica, giving the sherd a glittery appearance. Hand-made, grey and brown fabric.

Fabric 4: quartz-grain tempering
Fairly soft, handmade fabric with dark grey core and brown to buff surfaces. Tempered with white/semi-transparent quartz grains (*c.*1mm in size).

Crambeck reduced ware and calcite-gritted ware
National Reference Collection codes CRAM RE and HUN CG (Tomber and Dore 1998).

Catalogue

Access 19

There were two small sherds from a single vessel, likely to be local traditional ware. The small diameter vessel appears to have a plain rim reduced in width to form an external ledge (cf Swain 1987, fig. 45, no. 53), but the sherd is small and in poor condition (context 191010).

Access 27

This produced a small number of samian sherds in poor condition, each vessel represented by a single sherd. These were two Dr 18/31 bowls (*c.*120-150), a decorated body sherd, and a possible Curle 21 (second half of second century). Other second-century pottery included a campanulate bowl (Fig. 27, d)) and a small flanged bowl, both probably made locally. There were at least four vessels in local traditional wares; two jars (Fig. 27, a) and b)) and fragments of two squared rims from either a bowl or jar, probably from the same vessel (context 0053), as well as other body sherds. There was one sherd of calcite-gritted ware, likely to be fourth-century in date (Fig. 27, c)). The local traditonal ware could be residual, but local traditional ware has been found in association with fourth-century material

nearby at Butterwick Moor, Sedgefield, suggesting that the ware continues to be made throughout the Roman period.

Access 31

The fill of the pit **310204** produced the base of a thick-walled local traditional ware vessel (context 310205).

Access 37

This site produced the largest amount of pottery. There was a single, very small scrap of samian ware (context 0026), and a number of small sherds in grey wares without any diagnostic features, which could be second or third century in date. There were sherds from at least three different local traditional ware vessels from two areas of the site. Thick-walled sherds, likely to come from large bucket-shaped vessels, came from the ring-ditch (contexts 0097 and 0099), and sherds from two different vessels from ditch fill 26, associated with the samian (Fig. 27, e)).
The rest of the pottery dates to the late Roman period and comes from a number of different areas of the site. There were three sherds of Crambeck reduced wares, from more than one vessel, dating to the late third century or later, and three Huntcliff-type rims dating to 360+ (Fig. 27, f)).

Foundation 59

Undiagnostic scrap.

Catalogue of Illustrated Pottery

Figure 27

a) Jar, with sooting on exterior of rim. Six joining sherds, and smaller fragments. LTW Fabric 4. Ditch **0047**, Access 27.

b) Jar with squared rim, with sooting on exterior of rim and on body with an unsooted where the rim joins the body. Cf Catcote: Long 1988, fig. 3, nos 59-65. Two joining sherds. LTW Fabric 2. Context 0060, Ditch **0061**, Access 27.

c) Cooking pot, calcite-gritted ware. Layer **270100**, topsoil, Access 27.

d) Campanulate bowl. Gritty buff fabric with wide grey core, with plentiful quartz inclusions. Likely to be locally produced. Ditch **0047**, Access 27.

e) Plain-rimmed bowl, with external groove. Cf Thorpe Thewles: Swain 1987, fig. 47, no. 285. Small fragment of rim and single body sherd. LTW Fabric 1, oxidised surfaces. Context 0026, Ditch **0023**, Tower Foundation 5A, Access 37.

f) Cooking pot with Huntcliff-type rim, with an unusual flattened top. Calcite-gritted ware. Context 05011, Ditch **05012**, Tower Foundation 5A, Access 37.

Conclusion

The pottery assemblage consists of wares that are typical for the area and includes wares from the second century up to the very late fourth century. Of interest is the high proportion of

local traditional wares, and especially those pieces associated with possible fourth century pottery at Access 27 (and possibly also at Tower Foundation 5A, Access 37). The vessel forms in local traditional ware were first made in the Iron Age and continue unchanged into the Roman period, making it difficult to date them closely, but this association with fourth-century material may be an important indication that they continued to be produced up until the end of the Roman period.

Recommendations

No further work is recommended.

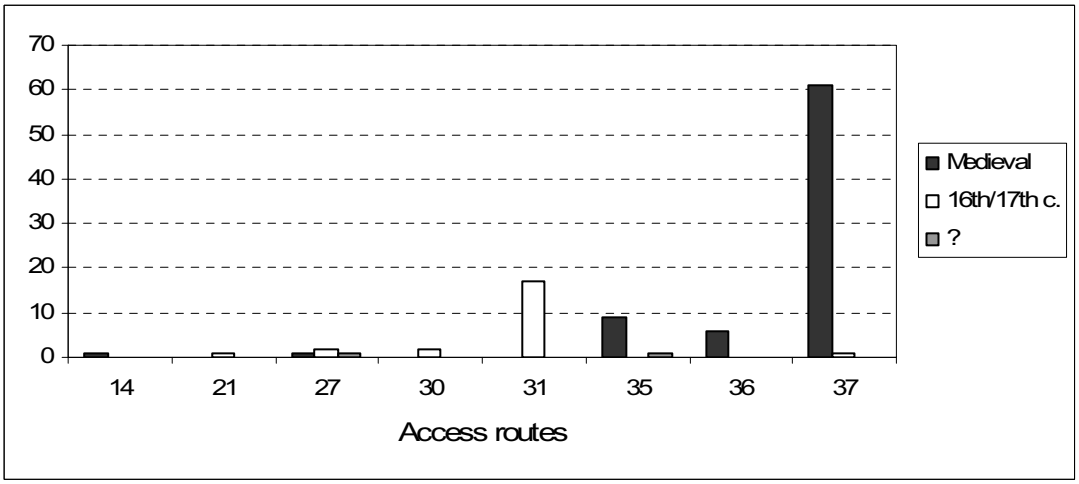
Appendix C Medieval Pottery

By Jenny Vaughan NCAS

Introduction

A small assemblage of 103 sherds of pottery weighing 835 grams was examined for this report. Sherds came from both the watching brief/monitoring phase of the project and from the 'set piece' excavations. The majority of the pottery was medieval with a date range of 12th to 14th century but 23 sherds were early post medieval (i.e. 16th/17th century). The distribution of the pottery relative to the access routes is shown in the chart below (using sherd count).



Pottery types present (see catalogue for further details)

There was a single sherd from 370800 of coarse gritted 'pimply' type possibly dateable to the 12th century. The majority of the medieval sherds were pink or buff fabrics. Many were small and otherwise undiagnostic, but a number of fragments had features characteristic of Tees Valley ware, eg. a bifid jar rim and a chamfered jug rim from context 0010.

Wrathmell has put forward a three part division of Tees Valley wares (Wrathmell 1987, 39-41, and 1990, 379-383): TVA - buff firing jars, TVB - more iron rich (pink to red) glazed wares, and TVC - softer, lighter pink fabric but with bands of white clay. In practice, and when dealing with small fragments, these types are not always distinguishable and many fragments (as in this small assemblage) have pink or light red cores with buff margins and surfaces.

There were six fragments of reduced green glazed (rg) pottery. One was a piece of base, the rest were body sherds. This type of pottery becomes dominant by the mid to late 14th century throughout the north east region.

For miscellaneous other medieval fragments see the catalogue.

The post-medieval pottery present was almost all either red earthenware or a type identified as 'local post-medieval'. This type is less iron-rich than the redware, firing to shades of buff, pink or orange, sometimes part reduced, and usually with greenish brown glaze. This is post-medieval coarseware typical of the 16th and 17th centuries. This type of pottery appears in the 16th century, for example at Hart (Addis 1976, 103), and in Hartlepool (Wrathmell 1987, 39), but similar pottery was being used in Durham in the later 17th/early 18th century (Ellison 1993, 96) and has been noted elsewhere by the current writer. Fragments from open vessels (dishes or bowls) and a possible jug were present. One fragment, probably not a local ware, had part of a design in red clay trailed onto the surface. There was also a red earthenware slipware rim of 17th century type. Slipwares are not known to have been made

in the region in the early post-medieval period. The other fragments of red earthenware may well also be locally made but there were no diagnostic features.

One interesting vessel was a dish in a buff fabric with internal green glaze and a well -formed rolled rim. This may be a continental import but has not been positively identified.

Methodology

The assemblage was sorted into types, and counts and weights per context recorded in an Access database table noting any form elements present.

Discussion

The small size, fragmentation and limited nature of this assemblage give little scope for discussion or interpretation, its main value being in the dating evidence it provides for activity in the areas from which it was recovered.

The medieval pottery was concentrated in the area of Access 37, Low Middlefield farm with sherds recovered during all phases of the project. It indicates 13th to 14th century activity in this area. Quantities from elsewhere were very small. The post-medieval pottery was concentrated at Access 31, East Close where no medieval pottery was found. The few sherds of reduced green glazed wares are the only indication of possible later medieval activity (i.e. later 14th/ 15th century) anywhere along the route of the overhead line.

Recommendations

There is no potential for any further work on this small group of pottery.

Appendix D Post-Medieval Pottery

Dr Anne Irving

Introduction

All the material was recorded at archive level in accordance with the guidelines laid out in Slowikowski *et al.* (2001). A total of 433 sherds from 333 vessels, weighing 5594 grams were recovered from the site.

Methodology

The material was laid out and viewed in context order. Sherds were counted and weighed by individual vessel within each context. The pottery was examined visually and using x20 magnification. This information was then added to an Access database. An archive list of the pottery is included in Archive Catalogue 1, with a summary in Table 1. The pottery dates from the Medieval to the early modern period.

Condition

The pottery is generally in abraded condition and shows signs of being redeposited.

Range

Medieval

Five vessels date to the medieval period: two are unknown wares which are probably local (MEDLOC), two Yorkshire Gritty wares (YG) and a single light firing ware which may be Stamford ware (ST) or a product of the recently discovered Pontefract kiln which produced Stamford-type wares.

Post Medieval

One hundred and twenty four vessels date to the post-medieval period. Many of these are earthenwares which were produced at many centres across Yorkshire and Staffordshire. Stoneware imports from the continent are also present (WEST, FREC).

Early Modern

Two hundred and two vessels date from the 18th to the 20th century. All the ware types present in the Spennymoor to Norton groups are extremely common in assemblages of this date. Several kiln props may also fall into this period.

Potential

All of the pottery is stable and poses no problem for long-term storage. No further work is required on the assemblage.

Provenance

Bridge House

Twenty-nine sherds of post-medieval and early modern pottery weighing 145 grams, and two fragments of pantile were recovered from topsoil (context 26000) and subsoil (26003).

Butterwick Road

Fourteen sherds of post-medieval and early modern pottery weighing 182 grams, and ten fragments of brick and tile were recovered from topsoil (context 270100), (270200), (270400), (271300), (271400), (271500), (28000) and subsoil (270803) and (271300). Modern drain pipe was recovered from cut **0074**.

Carlton

Forty-three sherds of post-medieval and early modern pottery, weighing 302 grams, were recovered from topsoil (context 01000) and subsoil (400503). Ten fragments of fired clay, weighing 188 grams, came from subsoil (01003).

Cooksons Green

Nine early modern sherds weighing 97 grams came from topsoil (context 050100), (050200) and dump (57004).

Cornforth

Three sherds of 19th to 20th century pottery, and two sherds of modern tile, came from fill of paelochannel (context 11406) and topsoil (55000).

Cornforth Lane

Five contexts produced post-medieval and early modern pottery: fill of paelochannel (context 13105), topsoil (130500), (52000) and layer (52003). A single sherd of 19th to 20th century pottery came from

(53004) fill of curvilinear **53005**. Early modern tile came from topsoil and layer (52000) and (52003), with a single example of Roman tile occurring in (52000).

East Close

A single medieval sherd came from subsoil (context 311603). A total of 53 post-medieval and early modern sherds from 50 vessels weighing 585 grams, and 13 fragments of modern tile, came from topsoil (21000), (22000), (310100), (310200), (310300), (310400), (310500) and subsoil (310203). Two fragments of pantile were retrieved from trackway (310405).

East Pasture House

Two sherds of late 18th to 19th century came from topsoil (context 120100).

Garmondsway Middle Farm

Six early modern sherds came from topsoil (context 41000) and (44000).

Grindon

Seven post-medieval and early modern sherds were retrieved from topsoil (context 361200), along with flat roofing tile from topsoil (09000) and fired clay (361200).

Hope House

Five sherds weighing 44 grams came from topsoil (context 3400), with a single fragment of non-diagnostic building material from soil overburden (0124).

Howden Hall

Ten sherds weighing 147 grams and a single fragment of pantile came from topsoil (context 380100), (380300) and subsoil (380303).

Low Middlewood

Nine sherds weighing 85 grams came from topsoil (context 370100), (370701) and (370800), along with building material of mixed date from fill of ditches **5012** and **370203**, remnant soil layer (0012) and subsoil (0022).

Metal Bridge

Ten early modern sherds were retrieved from topsoil (context 060100).

Norton

Twenty-eight sherds of early modern pottery, weighing 142 grams, were retrieved from topsoil (context 410100) and (410300).

Stobb Cross Lane

Sixty sherds from 52 vessels, weighing 673 grams came from six contexts. Two Yorkshire Gritty ware sherds were recovered from topsoil (context 140600). Four circular kiln props, of a type associated with early modern pottery production, were associated with topsoil (140600). The remaining pottery dates to the post-medieval and early modern periods and came from topsoil (140100), (140400), (140600), (141000), (51000) and cobbled track (140403).

Thinford

Thirteen sherds of post-medieval and early modern pottery came from topsoil (context 58000) and (59001).

Trimdon

Thirteen sherds of post-medieval and early modern pottery came from topsoil (context 210200) and (220100).

West Carrside Farm

A single late 18th to 19th century sherd and a fragment of pantile came from topsoil (context 250100).

Recommendations

No further work is required on this assemblage

Appendix E Ceramic Building Material

Dr Anne Irving

Introduction

All the material was recorded at archive level in accordance with the guidelines laid out by the ACBMG (2001). A total of 80 fragments of ceramic building material, weighing 5288 grams was recovered from the site.

Methodology

The material was laid out and viewed in context order. Fragments were counted and weighed within each context. The ceramic building material was examined visually and using x20 magnification. This information was then added to an Access database. An archive list of the ceramic building material is included in Archive Catalogue 2, with a summary in Table 2.

Condition

All the material is abraded and is likely to be redeposited.

Results

Table 1, Summary of the Ceramic Building Material

Cname	**Full name**	**NoF**	**W (g)**
BRK	Brick	11	1791

Appendix F The struck flint

By Hugo Anderson-Whymark

Introduction

Nineteen struck flints were recovered from excavations and a watching brief along the route of the ZXC overhead pylons. The majority of these flints were recovered from topsoil or the fills of comparatively recent archaeological features (e.g. furrows), but a few artefacts were recovered from undated ditches. The flints were in reasonably fresh condition, with the exception of a few that exhibited minor edge-damage; this potentially indicates that the majority of these flints may be close to their original places of deposition. The flint was of variable colour, including shades of orange, grey, white, light brown and light red, and where present the cortex was heavily abraded. The colour of the flints and condition of the cortex indicates that the raw material was obtained from a fluvial source, such as river gravels.

Results

The lithic assemblage was dominated by regular flakes although a small number of blades and blade-like flakes were recovered; the latter typically exhibited platform edge-abrasion. The flakes and blades are not intrinsically datable but the technology is most characteristic of the Mesolithic and Neolithic to early Bronze Age. Six retouched tools were recovered comprising a three scrapers, an edge retouched blade-like flake, a notched blade and an arrowhead (Fig 27 i)). The arrowhead is broken and missing its tip, but it is identifiable as a British oblique arrowhead dating from the late Neolithic through the presence of a single slight barb. The arrowhead is relatively crudely manufactured on a flake by the application of slightly invasive edge-retouch. The scrapers comprise an end scraper, a proximal end scraper and a thumbnail scraper. The latter is neatly manufactured and measures only 17 mm long by 16 mm wide and 7 mm thick. This artefact probably dates from the late Neolithic/early Bronze Age, but comparable small scrapers are occasionally recovered from Mesolithic assemblages. The other scrapers are not intrinsically datable. The notched blade exhibits two notches – one on the left hand side and the other on the distal end – and extensive use-wear on both sides. The notch on the side of the blade is A-symmetric and may result from an attempt to manufacture a microlith, potentially indicating the artefact is Mesolithic, but the presence of a second distal notch may indicate that the notches were produced as tools.

Conclusion

The lithic assemblage, although small, provides some evidence for Mesolithic to early Bronze Age activity in the landscape. The limited size of the assemblage however precludes accurate dating or consideration of the nature of the activity undertaken.

Recommendations

No further analytical work is recommended, but this report should be edited for inclusion in the publication and the arrowhead should be illustrated.

Catalogue

SPN35. Context 0063. Base of broken British oblique arrowhead. A single slight barb is present on the right hand side. Crudely manufactured with semi invasive edge-retouch. Late Neolithic

SPN35. Context 0063. Broken utilised blade with platform edge abrasion and dorsal blade scars. Mesolithic?

SPN16. Context 05000. Thumbnail scraper. Abrupt distal edge retouch forms a slightly curving distal edge. Addition slight abrupt retouch on the ventral surface on the right hand side forms a slight spur. 17 mm long by 16 mm wide and 7 mm thick. Late Neolithic/early Bronze Age?

SPN 16. Context 05006. Blade like flake with slight abrupt edge retouch on right hand side. Soft hammer flake with platform-edge preparation. Struck from regular blade-orientated core. Translucent orange brown flint. Mesolithic or early Neolithic?

SPN16. Context 52000. Leg D. Broken flake of gravel flint.

SPN 16. Context 090400. GPS 5102084. Flake of opaque mid grey flint. Moderate edge damage.

SPN 16. Context 090400. GPS 5102082. Broken flake of grey flint.

SPN 16. Context 090400. GPS 5102083. Flake of translucent light white gravel flint.

SPN 16. Context 190100. Proximal end scraper on a mid brown gravel flint flake. Smooth abraded cortex.

SPN16. Context 190103. Flake of opaque light red flint.

SPN 16. Context 190200. GPS 5110007. Utilised blade with notches in the left hand side and distal end. Date uncertain, but possibly Mesolithic.

SPN16. Context 211100. GPS 5110003. Burnt and broken end scraper exhibiting semi-abrupt edge retouch. Edge exhibits extensive use-wear.

SPN 16. Context 280100. GPS 5104007. Flake of translucent orange brown flint.

SPN 16. Context 280200. Broken flake of translucent orange brown flint.

SPN 16. Context 280200. Broken blade-like flake of translucent orange brown flint.

SPN 16. Context 280200. Chip of translucent orange brown flint.

SPN 16. Context 300200. GPS 5102208. Broken flake of an opaque mid grey flint.

SPN 16. Context 350300. GPS 5102031. Utilised flake of mid grey gravel flint.

SPN 16. Context 370100. Irregular waste or possibly unworked pebble of gravel flint.

Appendix G Report on the Recorded Finds and Treasure

Dr Kevin Leahy, FSA, MIfA

Introduction

The finds produced by this project were received in an 'as found' condition and no radiographs were available at the time of writing. It was found that the material was stable and in a generally good condition, although corrosion and concretions obscured some coins making a full identification impossible, they could only be classified by module.

Methodology

Objects were examined at x10 magnification using a binocular microscope, sketched and described in detail. Materials were identified visually and dimensions recorded using vernier callipers. Masses were obtained on an electronic balance to an accuracy of 0.01g. In the report the finds are listed in order of Context number and then by GPS number. Objects recovered as part of SPN 35 are placed at the end of the report.

Discussion

The archive contained 125 items which could be broken down by material as follows:

Copper alloy	Cupro-nickel	Glass	Iron	Lead	Pewter	Silver	Slag	Stone
83	1	1	10	23	2	3	1	1

It was found that 44 (35.2%) of the objects lacked any diagnostic features which would allow them to be identified and/or dated. Two Roman objects were present, a fourth century coin (context 220103) US and a fragment of a glass bangle (0053) <003>. There were two Medieval finds, a coin of Edward I (context 400403) and a lead spindle whorl (context 410300) GPS 3102321 which can be broadly dated to the twelfth to sixteenth century. The assemblage also included one item of treasure, a sixteenth century cast silver hairpin recovered during metal detecting (context 130101). The rest of the material was of recent date.

It was found that the numbers of finds from each period could be broken down as follows:

Undated	Roman	Medieval	16-17C	18C	19C	19-20C	20C
44	2	2	5	9	16	36	11

Although heavily biased towards later material this record does have a story to tell. Roman and Medieval material, while rare, shows that there was some activity in the area during these centuries. The increasing number of finds from the seventeenth century onward clearly shows the quickening of human activity. This is most evident in the dating of the 28 coins; there was one coin from the 350 years of Roman Britain, one from the whole of the Medieval period, one from the eighteenth century with the remaining 25 being nineteenth or twentieth century, all of small denomination.

Included amongst the finds is some metalworking debris; 13 pieces of casting spillage (four copper alloy and nine lead) and 12 metal off-cuts (nine copper alloy and three lead). These finds are, however, best seen as 'background noise' and it would be unsafe to see them as evidence for anything more than small scale, domestic metalworking. Although recent, some objects are historically interesting, the shell fragment (SPN 35; context 0100) representing Second World War anti-aircraft fire. The colliery tally (context 140100) GPS 5110017 shows an important local industry and the token from the 'West Cornforth Working Mens Store' (SPN 35, 26A) indicates the growth of the labour movement. The archaeological evidence presented by the finds gives a useful impression of the history of the area through which the pipeline passed.

Recommendations

It is recommended that two of the finds from this project should be published; the Roman glass bangle fragment (context 0053) <003>.and the Medieval lead spindle whorl (context 410300) GPS 3102321. The Roman fourth century coin (context 220103) and the coin of Edward I (context 400403) should be catalogued but not illustrated. No further action is required on any of the other finds.

Catalogue

Context:	(0053)	<003>	GPS
Material	Glass		
Condition:	Good but broken		
Description:	Fragment of a D sectioned, glass bangle with an original internal diameter of c. 60mm. It is made from an opaque, lustrous, off-white glass containing large numbers of small (up to 0.5mm diameter) bubbles.		
Dimensions:	Length 24.8mm; Width 10.4mm; Thickness 7.2mm		
Mass:	2.73g		
Identification:	Glass bangle

Context:	(220103)	<>	
Material	Copper alloy		
Condition:	Good		
Description:	Fragment of sheet copper alloy, two edges missing, a projection on one edge is curved backwards to form a broad hook.		
Dimensions:	Length 59.9mm; Width 41.2mm, Thickness 2.0mm		
Mass:	25.41g		
Identification:	Clasp		
Dating of find:	Recent		
Context description			
Further action	Not required		

Context:	(220103)	<>	US
Material	Copper alloy		
Condition:	Good, broken		
Description:	Cast buckle, originally double loop but one missing. Rectangular with rounded moulded corners, integral with the face of the buckle frame is a transverse ring, 10.7mm diameter. Bar slightly off-set, around it is a wrap-around pin.		
Dimensions:	Width 43.3mm; Length 26.7mm; Thickness 3.2mm		

Mass:	9.62g
Identification:	While this object resembles a sixteenth-seventeenth century sword suspender the loop is set at 90 degrees to that seen on these objects and the form of the off-set bar and pin suggests a later date. It is likely that this object is a harness fitting.
Dating of find:	Nineteenth century

Material	Copper alloy		
Condition:	Good		
Description:	Cast copper alloy plate, now distorted and broken. It originally consisted of a round ended bar with a 9.0mm diameter hole at each of its ends, one of which is now oval. Both sides of the bar's central section are expanded, with a large rounded projection on one side and a narrower lug on the other. Through the lug is a 7.0mm diameter hole. In the centre of the plate is a slot, 30.6 x 6.2mm one side of which bears of triangular		

projection, the other a corresponding notch. The plate has a general thickness of 2.0mm but around its edge 2.3mm wide x 2.0mm thick edging

Dimensions: Length 123.5mm; Width 61.2mm

Mass: 70.66g

Identification: Strap fitting from a box or harness

Dating of find: Nineteen-twentieth century

Artefacts classed as Treasure

Treasure Case: 2011 T575

PAS ID: FAKL-860142

Context 130101, Topsoil, Access 13

Date: Post-Medieval; 16th Century

Description: Cast silver pin, circular head with a cabled edge surrounding a raised heart above which is an oval hole. Soldered to the underside is a sharply pointed, S shaped pin, now crushed flat against the plate. This follows the line of a small projection on the edge of the disc.

Dimensions :

Length: 19.1 mm
Thickness: 2.2 mm
Diameter: 13.2 mm
Weight: 2.11 g

Discussion: This object is related to a well known group of sixteenth century dress fittings which Gaimster et. al. (2002, 157-196) described as 'cap hooks'. None of the examples described in his paper had the S shaped pin seen this object but the type is known from other finds, in particular the Farnham pin (Cherry, J. 'The Farnham pin', The Antiquaries Journal, 77, 1997, 388-393), see also Read (2008, 189-196) for this, and further examples. It is highly likely that Cherry's interpretation of these as hat pins is correct, the S shaped form of the pin shank ensuring that they were securely fixed into the fabric of the hat, something that would be difficult to achieve with a hook.

Consequently, in terms of age and as the object contains a minimum of 10% precious metal it qualifies as Treasure under the stipulations of the Treasure Act 1996.

Dr Kevin Leahy
National Finds Advisor

Appendix H The Faunal Remains

Jennifer Wood

Introduction

A total of 422 (1851g) refitted fragments of animal bone were recovered by hand during a scheme of archaeological works undertaken by Network Archaeology, along the route of an overhead cable project from Spennymoor to Norton.

The remains were recovered from a total of six individual sites across the scheme of works. The animal remains from each site are quantified within Table 1.

Table 1, Quantification of Remains, by Site

Site	Number	Weight (g)
Brandon House	1	1
Bridge House	3	7
Carlton	1	23
Cornforth Lane	2	5
Low Middlewood	414	1814
Redcar House	1	1
Total	422	1851

As can be seen, the majority of the assemblage was recovered from a single site: Low Middlewood. The animal bone from the additional sites were all recovered from topsoil, subsoil and a modern hedgerow and have therefore been omitted from further discussion.

The assemblage recovered from Low Middlewood which was characterised by a Romano-British settlement with overlying medieval furrows and a large medieval ditch at the southern extent of the site. The majority of the remains were recovered from ditches, ring ditches, a furrow and subsoil deposits.

Results

The remains were generally of a poor overall condition, averaging at grade 4 on the Lyman criteria (1996). Many of the remains were highly fragmentary and of general poor overall preservation, which may have limited the number of observable traits.

A single fragment of cattle metatarsal recovered from Romano-British ditch **0094** displayed evidence of butchery marks on the posterior shaft, consistent with meat removal.

A total of 14 fragments of animal bone recovered from Romano-British ditches **5031**, **5033** and **5037** displayed evidence of burning, which may be a result of incidental burning rather than cooking or method of disposal.

Three fragments of animal bone recovered from Romano-British ditch **0094** and medieval ditch **0025** displayed evidence of carnivore gnawing. The presence of carnivore gnawing suggests that dogs were present on site during both phases of occupation.

A single cattle astragalus recovered from Romano-British ditch **0094** had been purposely modified, with a single hole drilled through the centre. The function of the piece is uncertain; it may possibly have been used as a toggle or a gaming piece.

Table 2, Summary of Identified Bone

	Romano-British	Medieval	Undated	Total
Equid (Horse Family)	3			3
Cattle	26	10	1	37
Sheep/Goat	10			10
Pig	2			2
Dog *(Canis Sp.)*	1			1
Large Mammal	115	17	4	136
Medium Mammal	25	2		27
Unidentified	163	35		198
N=	345	64	5	414

As can be seen from Table 2, the most abundantly identified species were cattle, followed by smaller numbers of sheep/goat, *equid* (Horse Family), pig and dog *(Canis Sp.)* remains.

The assemblage is too small to provide meaningful information on animal husbandry and utilisation on site, save the presence of the animals on site. There is too little aging data surviving within the assemblage to suggest any generalised underlying patterns of animal husbandry.

As can be seen from Table 2, the assemblage is dominated by large mammals and large mammal size animal bone, which are more robust and therefore likely to survive in poor preservation conditions. Therefore the assemblage abundances of species identified may be affected by a bias of collection, rather than being a true representation of animal utilisation.

The skeletal elements represented suggest the remains were probably from a mixture of butchery discard and food waste.

Recommendations

No further work is required.

Appendix I Stone finds

By Gary Taylor

Introduction

Nine artefacts weighing a total of 5242g were recovered.

Condition

All of the other finds are in good condition.

Results

Table1, Stone

Cxt	Material	Description	NoF	W (g)	Date
0026	stone	Burnt stone, sandstone. One worn concave face, possibly used as whetstone	1	197	
	stone	Burnt stone, sandstone, 2 sets of 2 linking pieces	4	182	
0039	stone	Burnt stone, limestone	1	20	
05011	stone	Flaggy sandstone, 26mm thick, burnt. One side very smooth – paving?	1	675	
	stone	Burnt stone, sandstone, roughly square but no other evidence of use as building stone	1	215	
	stone	Natural waterworn dolerite cobble, approximately triangular section	1	3953	

Provenance

The other finds were recovered from ditch fills 0026, 0039 and 05011, all at Low Middlewood. All of the materials are probably fairly local to the area.

Range

All of the other finds are of stone, most of which is burnt. The majority of these are sandstone, though one is limestone. One piece may have been used as a whetstone while another is probably part of a paving slab. One very large piece is natural, being an approximately triangular cobble of dolerite. This is waterworn and the majority of the surface has weathered to a pale grey.

Conclusion

In general, the stones have limited potential but provide some functional evidence. Fires/hearths are indicated by the burnt stones and the piece of probable paving suggests the presence of tracks, yards or buildings. There is also a possible whetstone, although this may have been an ad hoc usage of a conveniently shaped stone as it does not appear to have been deliberately fashioned as a hone.

Recommendations

This group of artefacts is recommended for discard.

Appendix J Glass report

Mike Wood BA (hons) MLitt MIfA

Introduction

Thirty-nine items of glass weighing 4.3kg were recovered during an archaeological investigation along the route of the Spennymoor to Norton project. The material was derived from a variety of contexts including topsoil, subsoil a modern dump and the fill of a ditch and channel.

Methodology

The material was counted and weighed in grams, then examined visually to identify any diagnostic pieces and the overall condition of the assemblage. A summary of the material is recorded in Table 1.

Discussion

The assemblage contained a mix of forms spanning the later 19th and twentieth century including various bottles for food, drink and pharmacy related items. There was also the base of a finger oil lamp, fragments of glass tableware and window glass shards. A summary of the larger assemblages by site is discussed below.

Brandon House

Four artefacts likely dating from the 1930s-1940s were recovered from topsoil including an early Brylcreem jar, a Boutique Lentharic perfume bottle dating from 1936, and less accurately dated food and sauce bottle. The food bottle was stamped '*ff*', which may relate to the American bottle company Foster-Forbes, which produced similar products with this logo in the 1940s. This assemblage probably represents discard from household waste, which has gradually been spread over a field.

Carlton

A collection of late 19th century-early twentieth glass stoppers, chemist bottles and an ink bottle were recovered from topsoil and subsoil. This assemblage contains only larger more durable fragments and had suffered damage from ploughing suggesting it may have been part of a manure spread, gradually fragmented into smaller shards through agriculture in the 20th century.

Cornforth Lane

The largest individual assemblages along the route, ten items were recovered from the fills of a ditch and disused channel with artefacts spanning the end of the 19th century through to mid twentieth. Much of the assemblage was composed of sauce and food bottles suggesting either a dump of domestic waste or perhaps a nearby inn or public house disposing of empty bottles. A seemingly intact oil lamp was also recovered suggesting the upper shade or oil heating mechanism was damaged beyond repair.

Recommendations

The material warrants no further work or illustration. The artefacts are in a stable condition and require no conservation. All of the artefacts could be passed to suitable teaching collections, returned to the landowner or be discarded.

Appendix K Clay tobacco pipe report

Mike Wood BA (hons) MLitt MIfA

Introduction

Forty-five fragments of clay tobacco pipes were recovered from archaeological works along the Spennymoor to Norton project. The material was derived from topsoil and subsoil, with no stratified assemblages present.

Methodology

The material was counted and weighed in grams, then examined visually to identify any diagnostic pieces and the overall condition of the assemblage. Reference was made to published guidelines (Higgins & Davey 2004). Where no other identification has been possible, stems have been dated by established stem bore guidelines (Oswald 1975). It should be noted that dates provided by stem bore size can have an appreciable margin for error and are intended only as a general guide. A summary of the material is recorded in Table 1.

Discussion

The assemblage comprises a mixture of 19th century clay pipes, alongside earlier examples from the 18th and 17th centuries. There is also a single fragment which may date to the late 16th century to early 17th century, although this is based on a small fragment of wide-bored stem and should perhaps be viewed with caution.

Condition

Several of the pipes exhibit signs of weathering as would be expected from their recovery from topsoil and subsoil. Unsurprisingly, the earlier stems are small and heavily abraded, particularly the potential late 16th- early 17th century stem from Trimdon. Two stems from separate sites (Stobb Cross Lane and Trimdon) both exhibited a form of vitrified coating and suggest they had been heated to a high temperature, perhaps in a domestic hearth or a farm clearance bonfire alongside discarded glass.

Contexts of interest

Trimdon

This site produced three fragments of stem, two dating to the late 17th-mid 18th century and one small fragment of a potential late 16th to early 17th century pipe. This early fragment has a very large bore and has been rolled and weathered for some time.

Stobb Cross Lane

This site produced the largest assemblage, comprising thirteen fragments all dating from the end of the 18th to mid 19th century, when the village of Coxhoe expanded dramatically due to nearby mining (Bell's pit opened in 1827; Coxhoe Colliery 1935; West Hetton 1837; Cornforth Colliery 1838; Clarence Hetton Colliery 1839 and Bowburn Colliery in 1840). The size of the group may also be related to the proximity of this site to a branch of the Great North of England, Clarence and Hartlepool Junction Railway, which was opened at the southern end of Coxhoe village in 1839. The presence of labourers to create the line and later, engineers and passengers may have created more casual discard of broken pipes into

neighbouring fields. A pottery was established at Coxhoe in 1769, which began officially making clay pipes in 1851 as William Row (of the Row pipe making family) moved into the pottery. Pipe making lasted in Coxhoe until 1860 (Keys to the Past Coxhoe-accessed 23rd September 2011). This indicates by the mid-19th century, people in the village had ready access to such pipes as were found on this project, though by the mid 1800s clay pipes were readily available across the country.

East Close

The topsoil from this site contained a mixed selection of pipes including a group of nine late 17th to mid 18th century stems and bowls, four late 18th century stems and two early-mid nineteenth century bowls. This may suggest the topsoil has been frequently night soiled, including centuries of middened household waste onto adjacent fields.

Recommendations

None of the material warrants any further work or illustration. The complete bowls would, however, benefit from a photographic record. All the artefacts are in a stable condition and require no further conservation.

Table 1. Charred plant macrofossils and other remains from the Spennymoor to Norton electricity transmission network

Appendix L Environmental Report

Val Fryer, Church Farm, Sisland, Loddon, Norwich, Norfolk, NR14 6EF

Introduction and method statement

Excavations along the line of the Spennymoor (County Durham) to Norton (Teesside) electricity transmission network were undertaken by Network Archaeology. The work revealed pits, ditches, ring ditches and a kiln of probable Late Iron Age to Romano-British date, most of which were concentrated within the areas of Access route 27 and Tower Foundation 5A. Samples for the retrieval of the plant macrofossil assemblages were taken from across the excavated areas. Twenty-nine were taken during the course of the project, of which fifteen were selected by Network Archaeology for assessment. Those that were not assessed were considered to have low potential because they were either duplicate samples or were from isolated and undated features.

The samples were processed by manual water flotation/washover and the flots were collected in a 300 micron mesh sieve. The dried flots were scanned under a binocular microscope at magnifications up to x 16 and the plant macrofossils and other remains noted are listed in Table 1. Nomenclature within the table follows Stace (1997). All plant remains were charred.

The non-floating residues were collected in a 1mm mesh sieve and sorted when dry. Artefacts/ecofacts were not recorded.

Results

The recovered assemblages were all small (<0.1 litres in volume) and sparse, and it was noted that most of the remains, particularly within the features from Tower Foundation 5A, were severely weathered/abraded. It is currently unknown whether this was a result of the prolonged exposure of the material prior to deposition, or some subsequent disturbance of the deposits.

Barley (Hordeum sp.) and wheat (Triticum sp.) grains were noted (almost invariably as single specimens within an assemblage) along with a number of other cereals, which were too poorly preserved for close identification. Weed seeds occurred within only three assemblages. All were of common grasses (Poaceae) or grassland herbs (namely small legumes (Fabaceae)). A single fragment of hazel (Corylus avellana) nutshell was recorded within the assemblage from sample 004 (ditch [0061]). Charcoal/charred wood fragments were present at a low to moderate throughout along with pieces of charred root or stem, including fragments of heather (Ericaceae).

Small pieces of coal were present throughout, but at the time of writing it was unclear whether these were contemporary with the features from which the samples were taken, or later contaminants. Although some fragments of the black porous and tarry material were possible residues of the combustion of organic remains at very high temperatures, most were very hard and brittle, and were probable bi-products of the combustion of coal. Small fragments of severely weather bone were noted within all but six of the assemblages studied.

Conclusions

In summary, the composition of the three assemblages from Access Route 27 (samples 003, 004 and 005) is consistent with their being derived from small deposits/scatters of domestic hearth waste. Heather was often used as fuel within both domestic and light industrial contexts as it was easy to ignite and maintained an even, high temperature throughout combustion. It is assumed that it would also have been readily available within the local area.

The assemblages from Tower Foundation 5A are more difficult to interpret as all are very sparse. All would appear to be consistent with small scatters of refuse, possibly from within the kiln (cf the small pieces of burnt or fired clay), but the precise origin of the material is unclear. The near consistent presence of bone fragments may indicate that hides, meat or bones were being processed within the near vicinity, but it is not known if there is any corroborative evidence for this within the artefact assemblage from the site.

Recommendations

As none of the assemblages contain a sufficient density of material for quantification (i.e.100+ specimens), no further analysis is recommended. However, a summary of this assessment should be included within any publication of data from the site.

Appendix M The Post-Production residues

by Dr R. Mackenzie

Introduction

This report covers the post-excavation assessment of 12 fragments of slag-like residue recovered during archaeological fieldwork between Spennymoor, County Durham and Norton in Teeside. The aims of the assessment have been to try and identify the process origin of the residues by visual inspection, and establish whether there is potential for more detailed analysis of any of the fragments.

The results of the visual inspection are summarised below in Table 1.

Results

Context Number	Number of pieces	Approx. Weight	Type of material
05039	1	175g	Possible metalliferous slag relating to ferrous metal production.
05039	2	20g	Undiagnostic slag.
52000	1	112g	Undiagnostic slag.
55000	4	19g	Possible fuel ash slag (clinker).
55000	4	5g	Undiagnostic or possible fuel ash slag.

Table 1: Summary of slag residues recovered during archaeological fieldwork between Spennymoor and Norton.

Discussion

The three fragments from context 05039 are potentially Roman in date, the largest of the three weighs approximately 175g; although this fragment may relate to the smelting or smithing of iron, it is undiagnostic of a specific production method. The two smaller fragments recovered from context 05039 are very heavily weathered and it has not been possible to determine whether these are metalliferous in origin.

The remainder of the assemblage consists of either possible fuel ash or undiagnostic slag. It is worth noting that contexts 52000 and 55000 are undated topsoil layers. Fuel ash slag can be produced as a by-product of wood or coal fuelled fires that are burnt over a relatively long period, so slag recovered could relate to either a domestic source, such as a cooking/heating hearth, or 'industrial' source, such as the firebox from a steam boiler or hearth of a mobile blacksmith/farrier.

In some cases, scientific analysis can help to determine the process origin of slag, although this is normally only justified where there is supporting archaeological or historical evidence, or the particular slag found is of an archaeometallurgically significant type.

Conclusion

The only item of note in the assemblage is the fragment of possible metalliferous slag recovered from context 05039, which is thought to date from the Roman period. Supporting evidence of iron smelting or smithing does not appear to have been found, which makes it

difficult to justify any further analysis of the fragment of slag; however, the presence of this fragment of slag should be noted for any future archaeological research in the area.

Recommendations

The presence of the fragment of possible metalliferous slag should be noted in the site archive. The fragments of undiagnostic and possible fuel ash slag recovered are of limited archaeological significance and no further action is required.

No further analytical work is recommended on any of the slag assemblage covered by this assessment, and the fragments can be disposed of in the usual manner.

Appendix O

Sites with no or minimal archaeology

Results of the strip, map and record and watching brief on negative sites

County Durham						
Access	Name	Description	Land-use	Ht OD	NGR	
Access 6A	Metal Bridge	Several pieces of modern pottery were located within the topsoil. Beyond these finds, there was nothing of archaeological interest found during the monitoring.	Arable	80m	430171	535226
Access 9	Brandon House	A former hedge line **56005** and a modern trackway **090404** were revealed. A layer of 20th century household waste artefacts had been dumped across the site and probably represents a minor levelling episode.	Arable	80m	430416	534586
Access 11	Cornforth	The frame from a recent pen-knife, a George V half penny, a George VI penny, a copper alloy off-cut and a 19th or 20th century cast metal poker finial were all recovered during the metal-detecting survey. The probable route of the extant Coxhoe Beck **110405** was located on the south to north-west curve of the track. The beck has not been utilised as a water system for some time, and was likely dammed and backfilled in the early 20th century	Arable and grazing	90m	431196	535081
Access 12	East Pasture House	Several fragments of modern pottery were recovered from the topsoil. With the exception of the pottery, nothing of archaeological interest was located during the monitoring	Arable and grazing	90m	431005	535016

Access 13	Cornforth Lane	A 16th century silver hairpin (Appendix G) was recovered from topsoil during the metal-detecting survey, this item as been classed as treasure. There is nothing to suggest the hairpin is anything other than casual loss, presumably from a traveller passing near the village of Cornforth, which is known to have existed since at least the 12th century. Further traces of the former Coxhoe Beck **130104**/**53005** were located. The circular earthwork, D8016, which is recorded as been present within the vicinity of tower ZXC12 may be part of the former Coxhoe beck.	Grazing	95m	431761	534797
Access 15	Garmondsway	No archaeology was revealed, despite the presence of the nearby Deserted Medieval Village of Garmondsway.	Arable	140m	433145	534514
Access 16	Harap Road	An undated ditch **46004** was aligned east to west near a north-east to south-west aligned palaeochannel **46007/46011**. Neither feature produced any dating evidence.	Arable	150m	433510	534440
Access 17	Garmondsway Middle Farm	Despite the presence of the nearby DMV of Garmondsway, the only archaeological material recovered was 18th and 19th century in date and derived from topsoil.	Arable	150m	434048	534317

Access 18	Greenside Farm	The lack of archaeological features and artefacts suggests the discovery of a single metal-detected 18th century bronze buckle represents accidental discard and does not suggest any nearby buried remains	Arable	160m	436183	534237
Access 22	Trimdon Grange	No archaeology was present. However, the metal-detecting survey recovered: a 4th century Roman coin; two bronze buttons (18th to 20th century) , a bronze buckle and a bronze clasp (both dating to the 19th-20th century) and a bronze spill.	Arable	130m	436518	533160
Access 23	Salters Lane	No archaeology or finds were present.	Arable	120m	436726	532828
Access 24	Hope House	No archaeology or finds were present.	Arable	110m	436882	532642
Access 25	West Carrside Farm	A 20th century copper sixpence was recovered during metal-detecting as well as modern pottery and tile.	Arable	110m	436183	534237
Access 26	Galley Law Farm	No archaeological remains were present beyond evidence of casual stone clearance from farmland, which could have happened at any point in the last few centuries and bioturbation from tree roots encroaching across the access	Arable	100m	437042	532381
Access 28	Three Horse Shoe Inn	An 18th century bronze buckle and 20th century copper coin were recovered during metal-detecting.	Arable	100m	437335	531754
Access 29	Bridge House	Modern pottery was recovered from topsoil.	Arable	100m	437388	530004

Access 30	Redcar House	No archaeology was present. However, worked flint, animal bone, medieval pottery and modern cbm were recovered from topsoil.	Arable	100m	437537	529680
Access 33	Green Hill	A partial track way **330304** was revealed, which may have provided access to a farm or ancillary storage sheds.	Arable	90m	437466	529093
Teeside						
Access	Name	Description	Land-use	Ht OD	NGR	
Access 36	Grindon	No archaeology was revealed, despite proximity to a number of known medieval sites including the shrunken medieval settlement of Grindon, the deserted medieval settlement of Fulthorpe and nearby remnants of field systems.	Arable and Grazing	80m	441024	524687
Access 38	Howden Hall	Modern pottery, cbm and glass were collected from topsoil.	Grazing	45m	441144	523114
Access 39	Middlewood	No archaeology was revealed despite the proximity to a medieval field system (T 699). An 18th century bronze eyelet was recovered during metal-detecting.	Grazing	45m	441195	522899
Access 40	Carlton	This site revealed no archaeological features; however it did produce a large number of finds from topsoil including; modern pottery, glass, clay tobacco pipes, a 13th century coin and forty-five 18th-20th century metal finds.	Arable	45m	440961	522619

Access 41	Norton	No archaeology was present. Topsoil finds included; clay tobacco pipe, modern pottery and glass, a medieval lead spindle whorl and three 18th-20th century metal items (an off-cut, a fitting and a spoon).	Arable	50m	440670	522004

OASIS ID: networka2-120080

Project details

Project name	Spennymoor to Norton
Short description of the project	Linear overhead cable project from County Durham to Teesside. Two Romano-British sites were revealed.
Project dates	Start: 04-01-2010 End: 30-09-2011
Previous/future work	Yes / Not known
Any associated project reference codes	SPN - Sitecode
Type of project	Recording project
Site status	None
Current Land use	Cultivated Land 2 - Operations to a depth less than 0.25m
Monument type	RIDGE AND FURROW Medieval
Monument type	SETTLEMENT Roman
Significant Finds	POTTERY Roman
Significant Finds	METALWORK Post Medieval
Investigation type	'Part Excavation','Systematic Metal Detector Survey','Watching Brief'
Prompt	Direction from Local Planning Authority - PPS

Project location

Country	England
Site location	DURHAM SEDGEFIELD SPENNYMOOR Butterwick Road
Postcode	TS21 4BE
Study area	500.00 Square metres
Site coordinates	NZ 376 311 54.6734519375 -1.416877038640 54 40 24 N 001 25 00 W Point
Lat/Long Datum	Unknown
Height OD / Depth	Min: 90.00m Max: 100.00m
