CONCISE SUMMARY OF REPORT

In December 2019 Vindomora Solutions Ltd were commissioned by Strutt and Parker on behalf of their client, Mr. Phil Farmer, to undertake a scheme of archaeological evaluation on land to the south and southeast of James Calvert Spence College, Acklington Road, Amble. The need for the evaluation was identified by the Local Authority as pre-determination for planning application 16/04305/OUT, in line with paragraphs 189, 190, 197 and 199 of the National Planning Policy Framework. The proposed application will see the construction of 500 residential units with associated access, public open space, landscaping and amenity space.

56 trenches were excavated totalling 3024m² or 4% of the overall evaluation area as stipulated in the agreed Written Scheme of Investigation. The trenches were excavated by a 14 tonne JCB with 1.8m wide toothless ditching bucket under constant archaeological supervision. Once excavated, the trenches were cleaned using hand tools and recorded before being backfilled.

No archaeological remains of interest were observed within the evaluation area, with artefacts (with the exception of the two sherds of background 16th century pottery) dating from the Victorian period through to the late 20th century. The potential archaeological features noted on the geophysical survey (AOC 2017) can be explained through the presence of crossing furrow systems, the field drain network and pockets of coal and ash in the overburden.

Figure 1. Location of the site, regionally.

1. SCOPE OF PROJECT

Plate 1. Aerial view of the development area (dataset © 2020 Google).

1.1 Project location

- 1.1.1 The evaluation area lies within land to the south and southeast of James Calvert Spence College, Acklington Road, Amble, Northumberland (centred at NGR 425799,603500). The area outlined in red does not constitute the whole of the proposed development area, but the eastern extent of the development lies over the Togston open cast mine and as such is not included in this evaluation. *Figure 1* locates the site regionally with *Figure 2* showing the site locally.
- 1.1.2 **Geology:** The proposed development area (PDA) lies over the Pennine Lower Coal Measures Formation, comprising interbedded sandstone and mudstone with occasional coal seams. Over this lies Diamicton till mainly composed of clay, gravel and sand (British Geological Survey, 2020).
- 1.1.3 The site lies at an average of 18m OD (*Ordnance Datum*, above sea level) at its northwestern extent, sloping down to 11m OD at its southeastern extent.

1.2 Circumstances of the Project

- 1.2.1 In December 2019 Vindomora Solutions Ltd were commissioned by Strutt and Parker on behalf of their client, Mr. Phil Farmer, to undertake a scheme of archaeological evaluation on land to the south and southeast of James Calvert Spence College, Acklington Road, Amble. The need for the evaluation was identified by the Local Authority as pre-determination for planning application 16/04305/OUT, in line with paragraphs 189, 190, 197 and 199 of the National Planning Policy

Framework (2019). The proposed application will see the construction of 500 residential units with associated access, public open space, landscaping and amenity space.

- 1.2.2 Archaeological and historical research objectives are built into developer funded archaeological schemes of work. This is the result of a number of English Heritage national policy frameworks: *Exploring our Past* (1991), *Frameworks for our Past* (1996), *Research Agenda* (1997) and *Policy Statement on Implementation* (1999). The research priorities proposed initially to have potential direct relevance to this project are set out in *Shared Visions: North East Regional Research Framework for the Historic Environment* (2006), in particular:

- | | |
|--------------|--|
| Prehistoric: | iii. Settlement;
iii. Landscapes;
iv. Material culture |
| Roman: | Riv. Native and civilian life;
Rv. Roman material culture;
Rix. Landscape and environment. |
| Medieval: | MDi. Settlement;
MDii. Landscape;
MDvii. Artefacts. |

1.3 Written Scheme of Investigation

- 1.3.1 The Written Scheme of Investigation (WSI) for this project was produced by Tony Liddell, Principal Archaeologist for Vindomora Solutions Ltd and approved by Nick Best, Assistant County Archaeologist for Northumberland Conservation (Version 2, dated 5th March 2020).

1.4 Timetable of works

- 1.4.1 The fieldwork was undertaken between 17th March and the 27th March 2020.
- 1.4.2 The results of the inspection and survey were compiled into this report during the week commencing the 20th April 2020, with the report finalised on Monday, May 11, 2020.

1.5 Professional standards

- 1.5.1 The work undertaken was in accordance with the Chartered Institute for Archaeologists' *Code of Conduct* (2014) and their *Standard and Guidance for an archaeological evaluation* (2014). Standards were also in accordance with the British Archaeologists' and Developers' Liaison Group's *Code of Practice* (1988).

1.6 Health and safety

- 1.6.1 Standard PPE was utilised for health and safety purposes throughout the fieldwork. All issues of on-site health and safety were undertaken in accordance with the Vindomora Solutions Limited *Health and Safety Manual* (updated 2018). COVID-19 restrictions were adhered to through the length of this project.

1.7 Archive

- 1.7.1 A full archive has been compiled in line with the specification and current UKIC and English Heritage Guidelines. The project code is **ARA-20 (Acklington Road Amble 2020)**. Vindomora Solutions Ltd support the **Online Access to the Index of Archaeological Investigations** project (OASIS). As a result, this report will be made available to the project under the unique identifier **vindomor1-393917**.

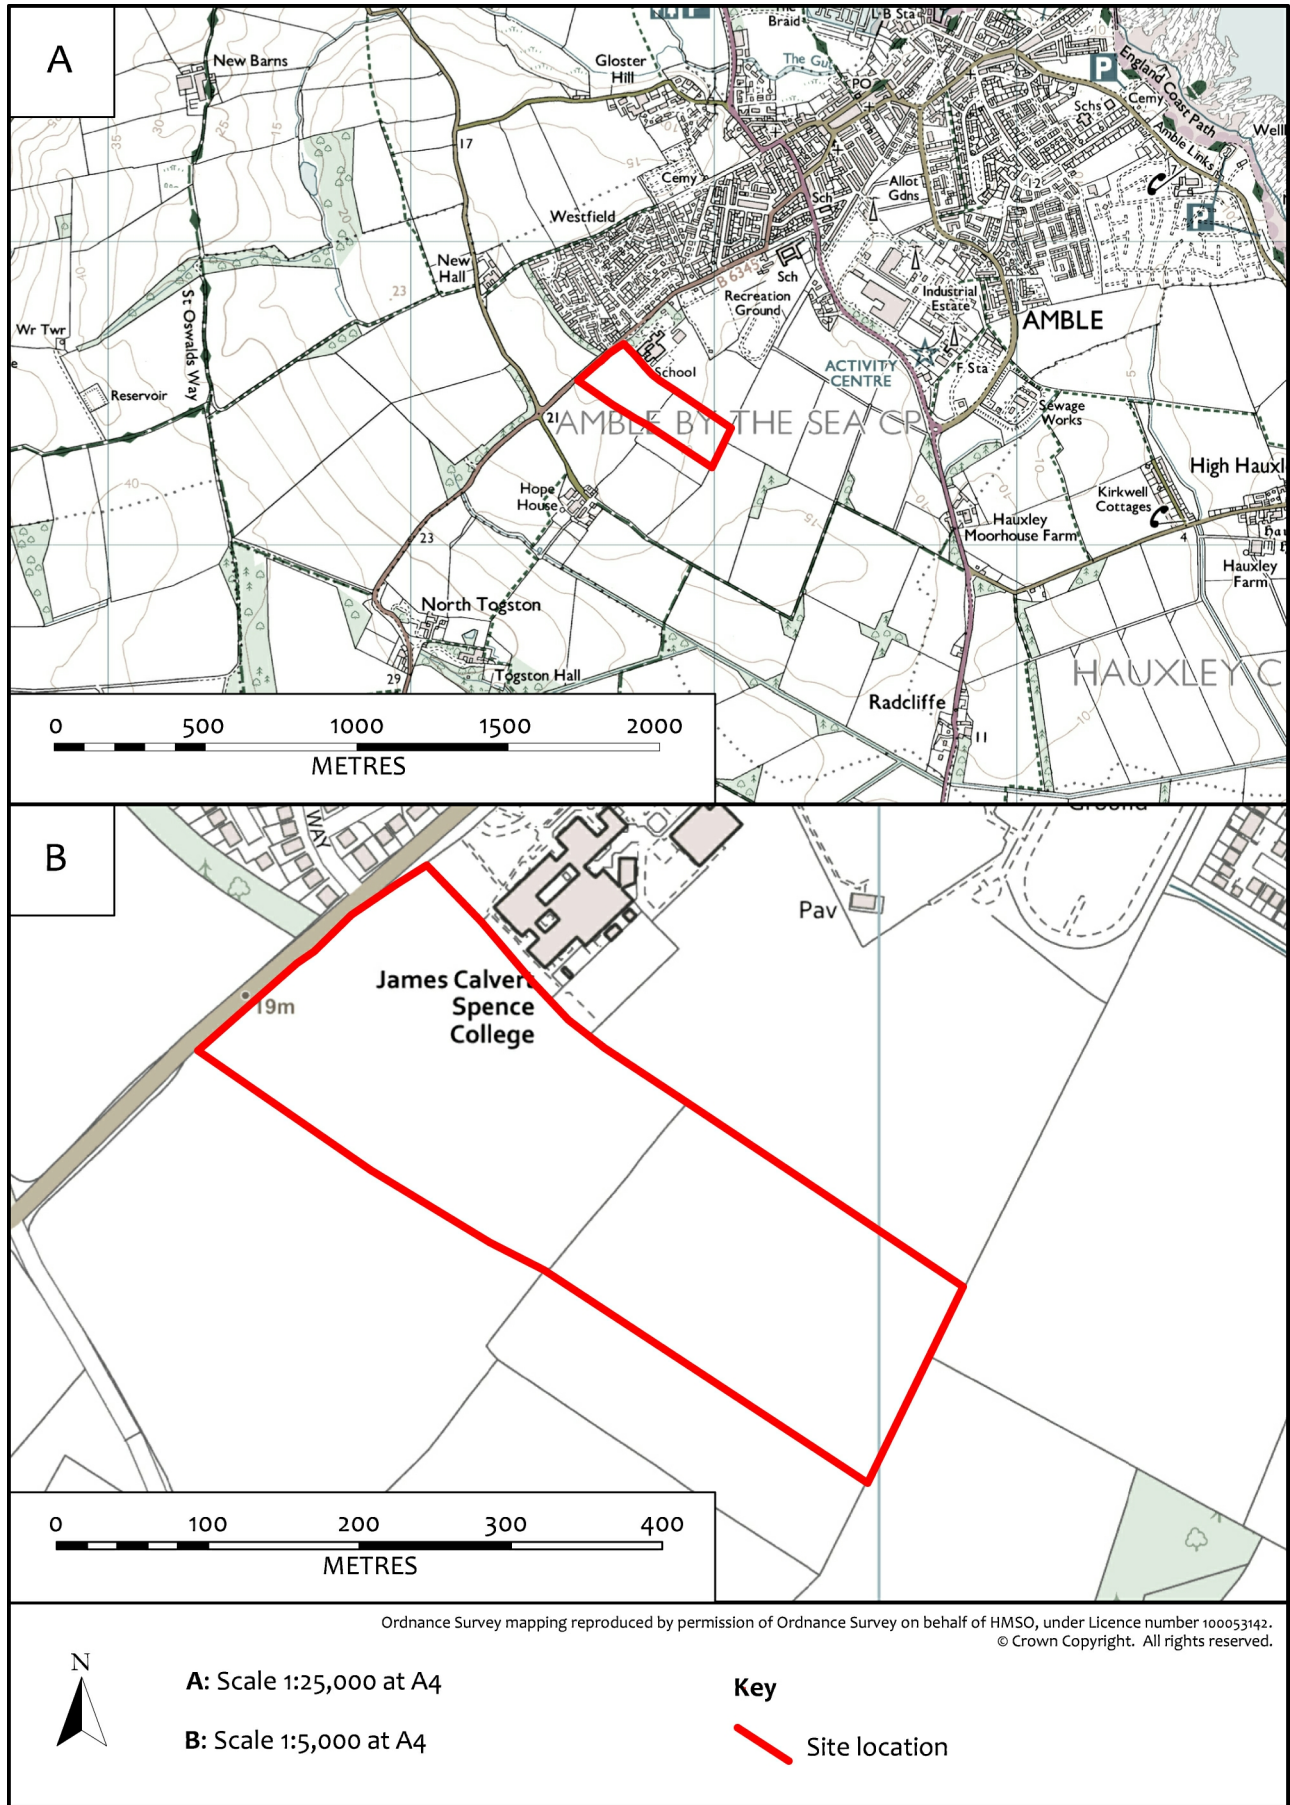

Figure 2. Location of the site, locally.

2. ARCHAEOLOGICAL BACKGROUND SUMMARY

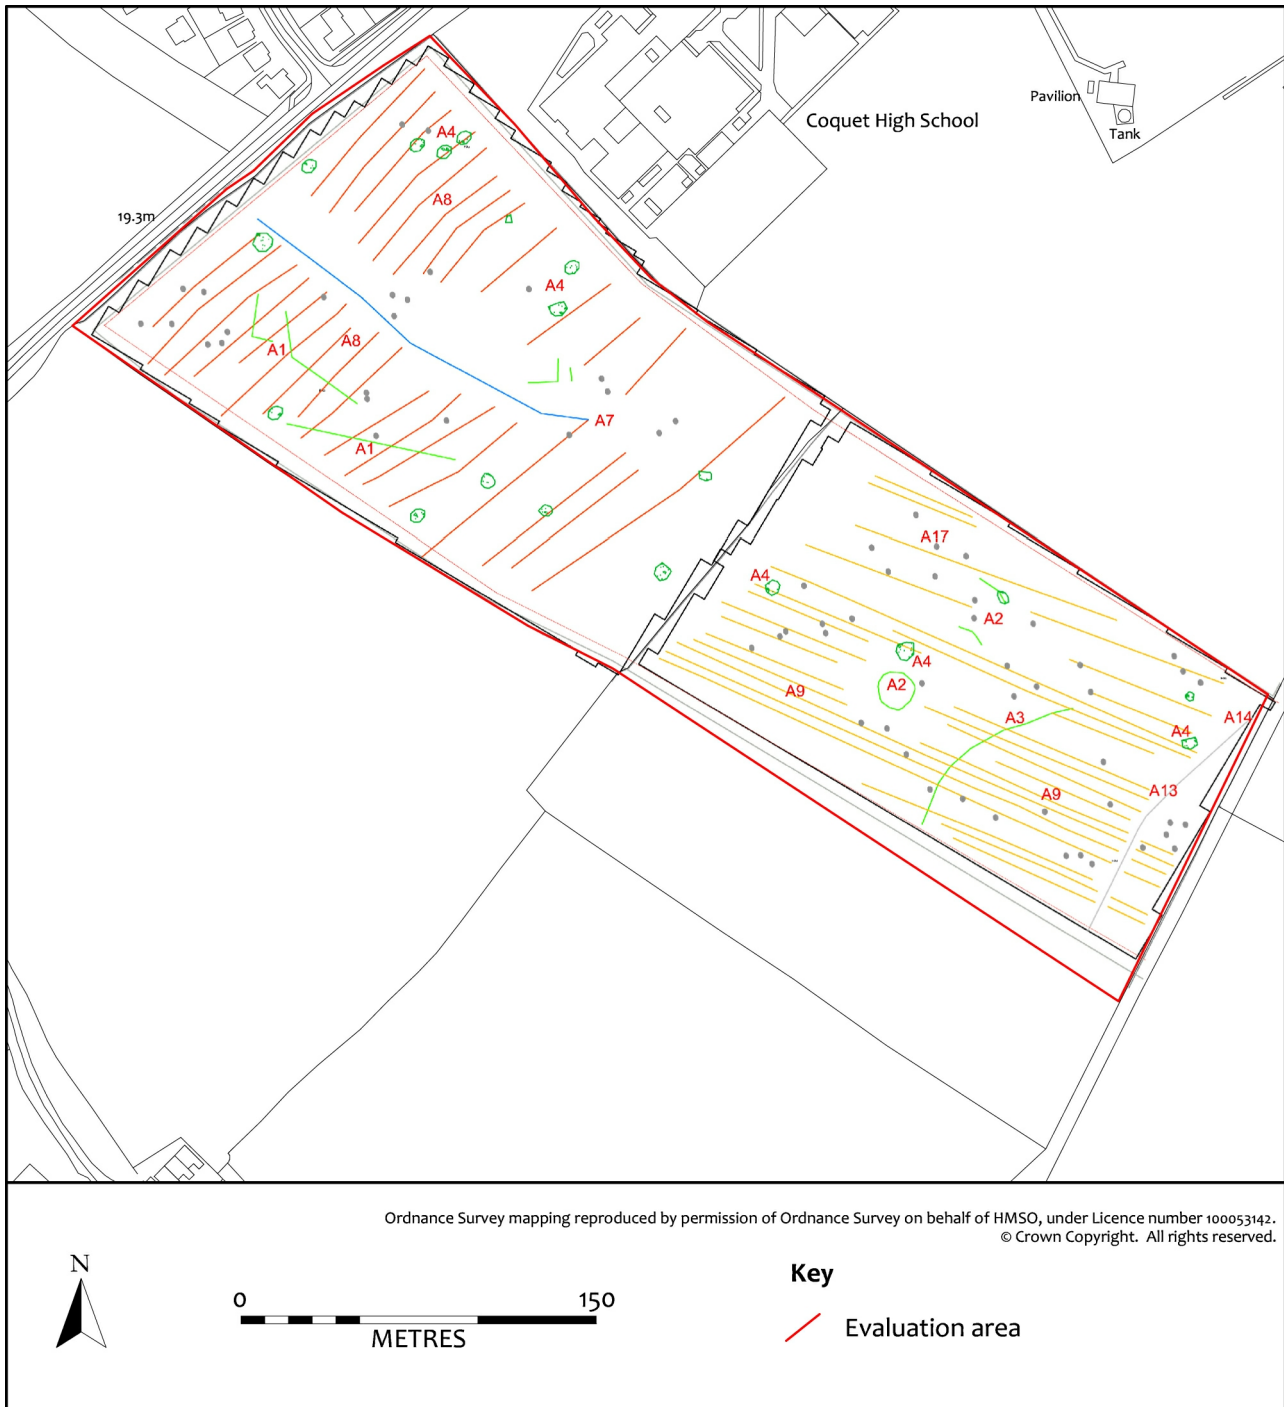

Figure 3. AOC's geophysical survey interpretation. The yellow and red lines are ridge and furrow with the green denoting potential archaeological remains and the grey dots magnetic anomalies.

2.1 Summary

- 2.1.1 The historical/archaeological background is based primarily upon data from the Archaeological Desk-based Assessment produced by Archaeological Services Durham University in 2016 as well as a geophysical survey undertaken by AOC Archaeology Group in 2017 and LIDAR data.

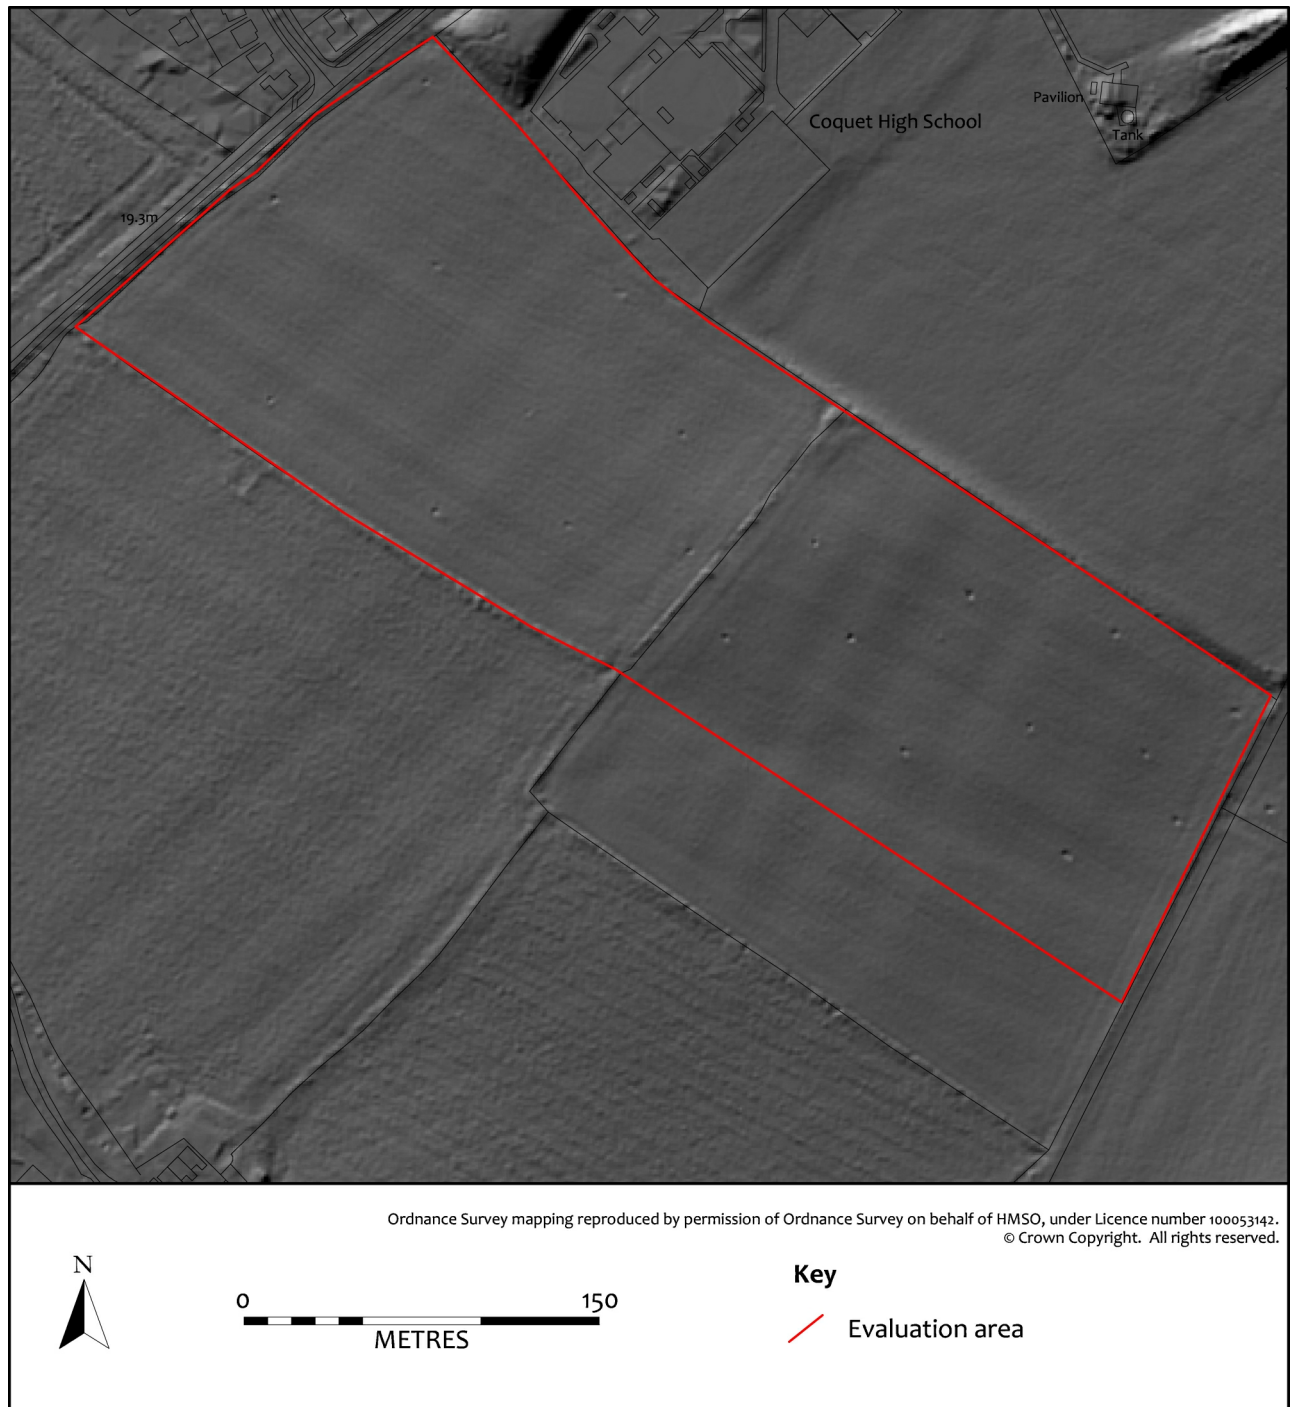

Figure 4. LIDAR imagery of the site clearly showing the location of the Togston geotech pits.

- 2.1.2 The desk-based assessment states that "There is no direct evidence for prehistoric or Roman activity within the proposed development area, but the presence of activity in the study area [1km radius of the site] indicates that an as yet unidentified resource has the potential to exist within the site... The proposed development area was probably agricultural land during the medieval and post-medieval periods. Evidence relating to this in the form of cultivation remains has been identified from aerial photographs and has the potential to exist on the site, but is of limited significance."
- 2.1.3 The geophysical survey undertaken in 2017 concluded that "The results of the survey identified no definitive archaeological anomalies within the survey area. A number of tentative discrete linear, rectilinear and curvilinear trends possibly archaeological, have been located within the

survey. Several responses of unclear origin were also recorded although these are considered most likely to be the result of geotechnical trenches and boreholes and previous open cast mining remains. A number of agricultural anomalies have been observed in the data including a former field boundary and a second possible field division, as well as ridge and furrow ploughing and more modern ploughing trends. Clear linear trends of field drainage have also been detected in a herringbone shape within the survey. Several modern services were recorded close to the herringbone drainage and could be culverts or drainage pipes. Associated manhole covers were also detected and visible on the surface in these locations. An area of magnetic disturbance, most likely the result of a former railway was also recorded, as was the edge of the former opencast boundary. Throughout the survey area isolated dipolar or ferrous (iron spikes) anomalies were also recorded; these are most likely the result of manuring and modern detritus." A plot of the geophysical results can be seen in *Figure 3*.

- 2.1.4 *Figure 4* shows a LIDAR plot of the evaluation area showing a southeast-northwest ploughing regime as well as clearly showing the location of the Togston geotechnical investigations.

2.2 Archaeological Potential

- 2.2.1 The archaeological potential of the site was unknown, though the presence of Prehistoric, Roman and medieval archaeology in the nearby vicinity suggested a moderate potential for archaeological remains relating to those periods lying within the development area. The geophysical survey undertaken in 2017 suggested the potential for linear and cut anomalies that may have represented pre-medieval activity as the anomalies appear to be beneath the remains of the medieval ridge and furrow system. The LIDAR shows little else, barring helping to resolve the location of the 20th century Togston geotechnical investigations.

3. THE EVALUATION

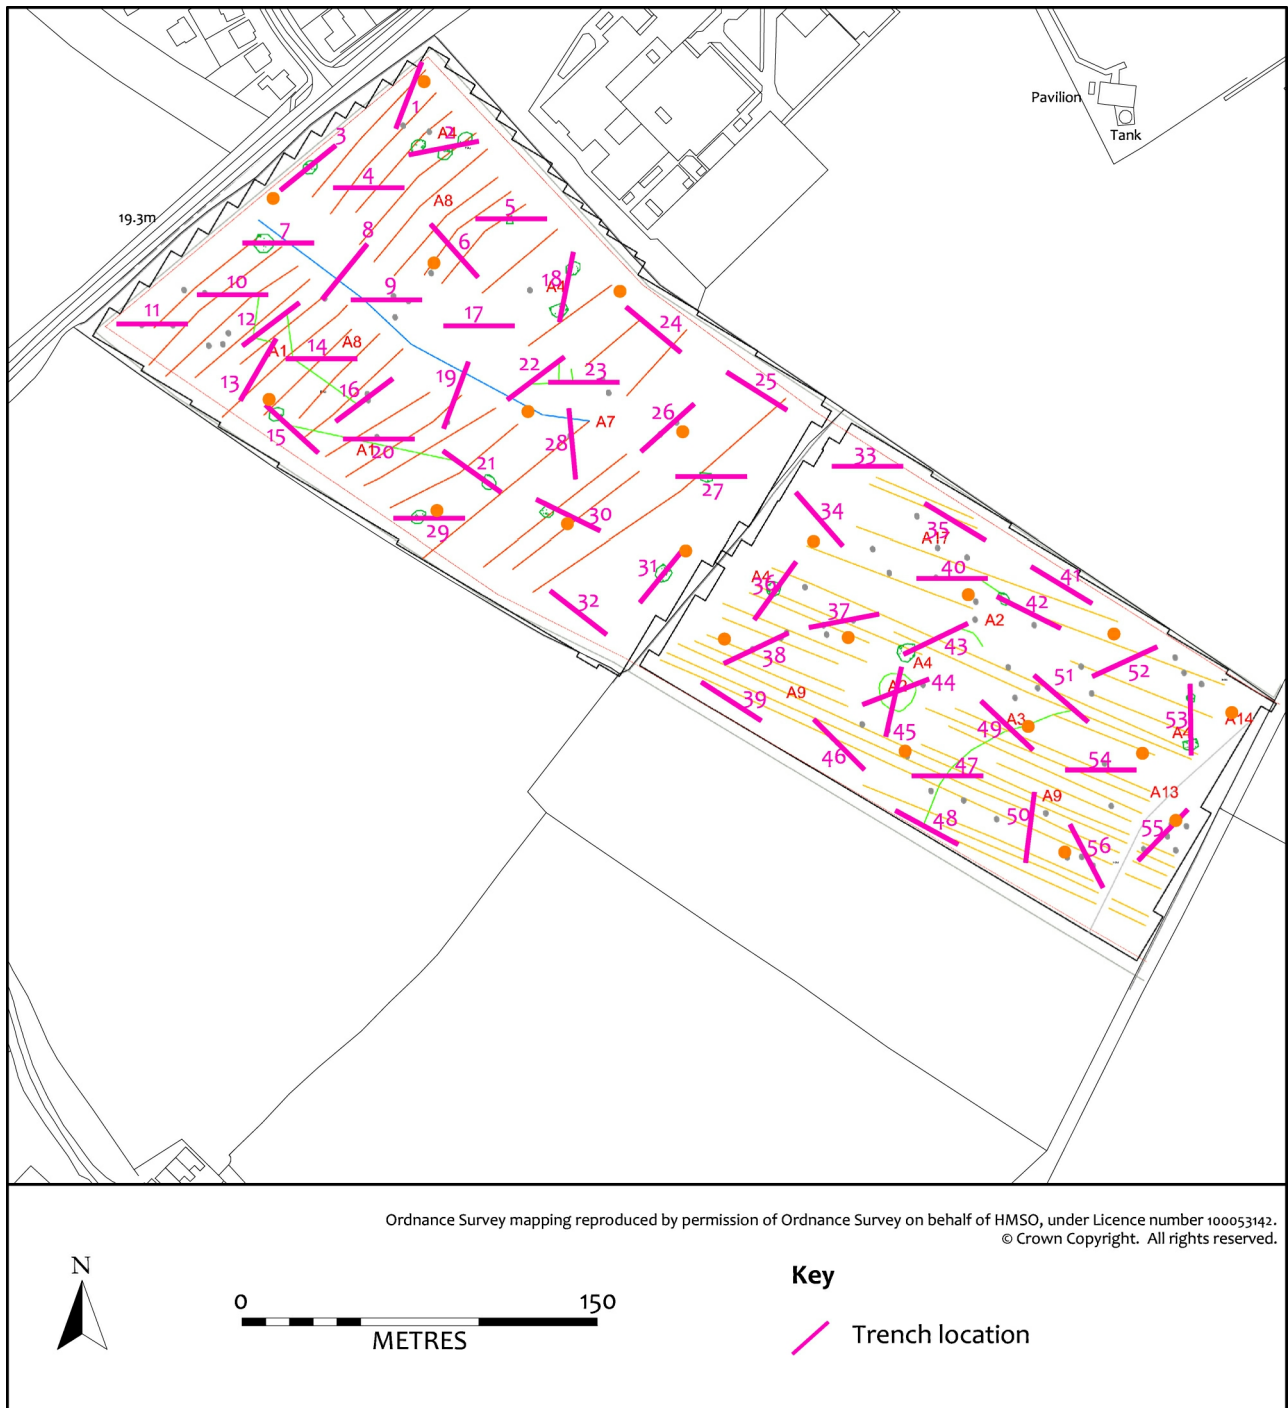

Figure 5. Trench location plan.

3.1 Introduction

- 3.1.1 All trenches were located via Leica GPS Rover based upon the agreed layout in the Written Scheme of Investigation. The level of accuracy recorded by the GPS system lay within 0.02m, allowing for accurate placement.
- 3.1.2 The trenches were excavated by a 14 tonne JCB with 1.8m wide toothless ditching bucket under constant archaeological supervision. The machine and driver were supplied by D&K Plant Hire.

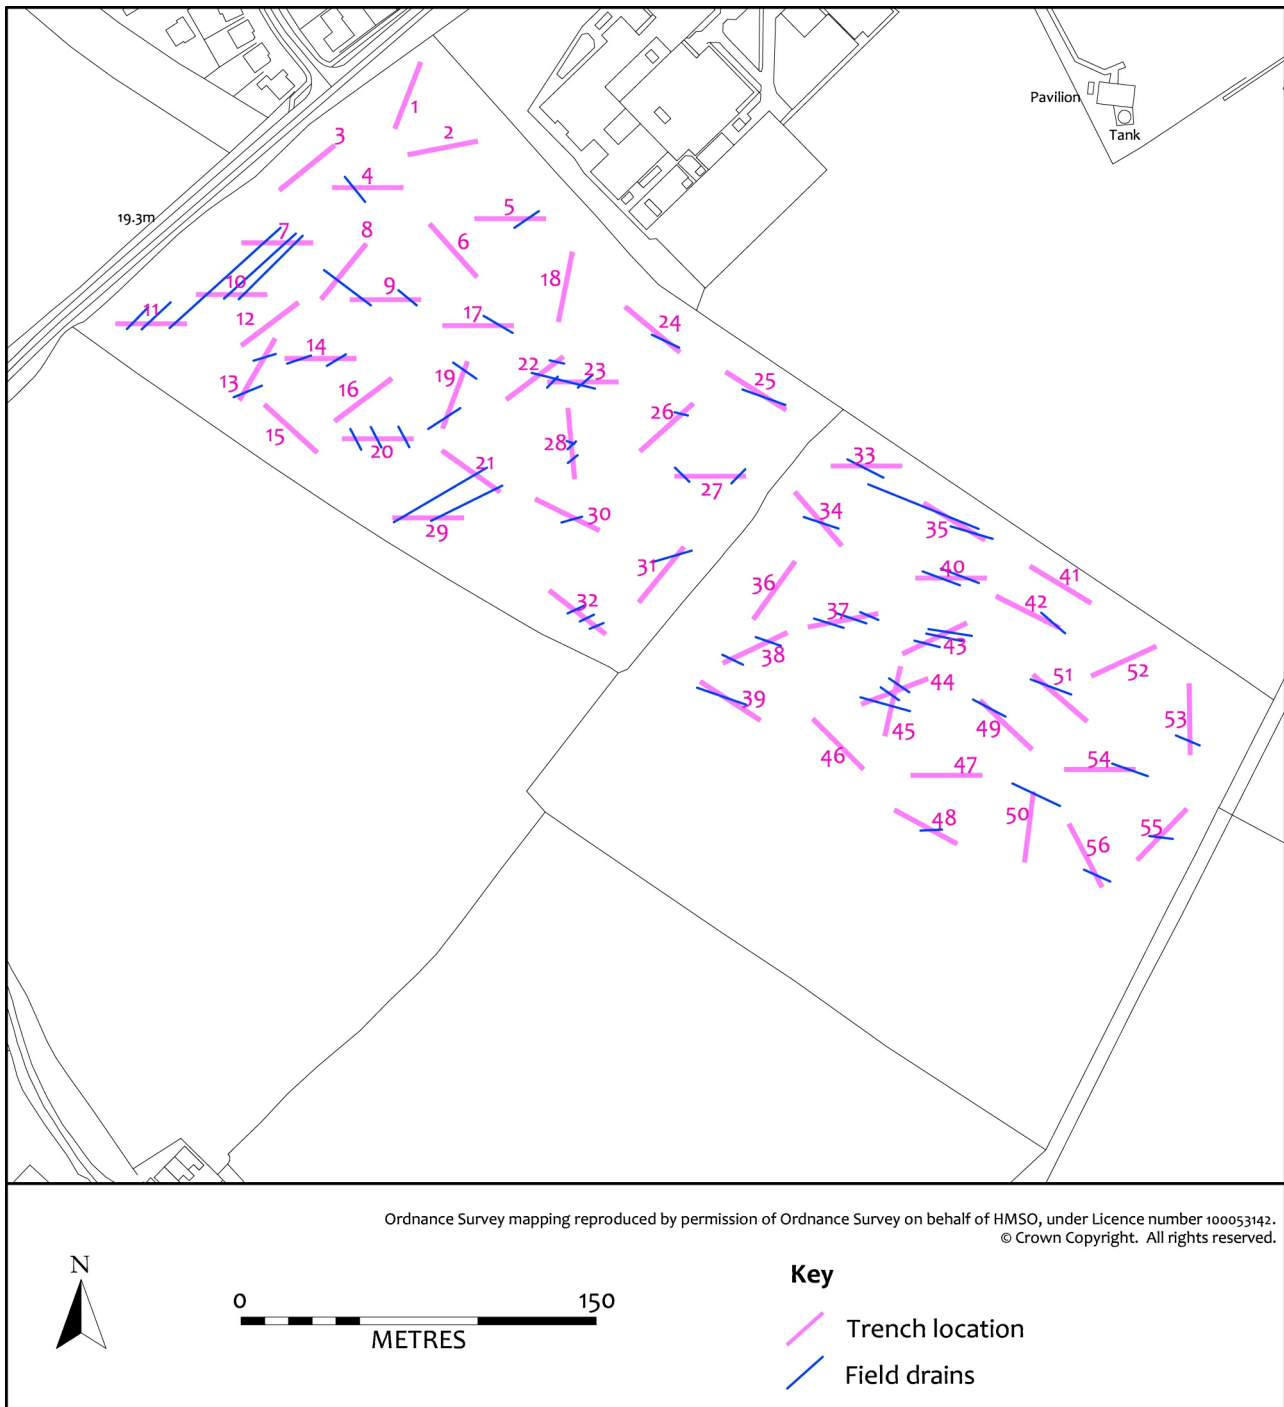

Figure 6. Location of field drain network identified in the evaluation.

- 3.1.3 56 trenches were excavated totalling 3024m² or 4% of the overall evaluation area as stipulated in the agreed Written Scheme of Investigation. Figure 5 shows the trench layout.
- 3.1.4 For ease of interpretation a single context system was used to record the site. Contexts (each context represents a different element or event) are identified in blue, with rounded brackets for deposits and fills, eg (#) for context identifier #1, and in squared brackets for cuts, example [#]. Geological contexts are identified in green with rounded brackets, to differentiate from archaeological contexts, eg (G#).

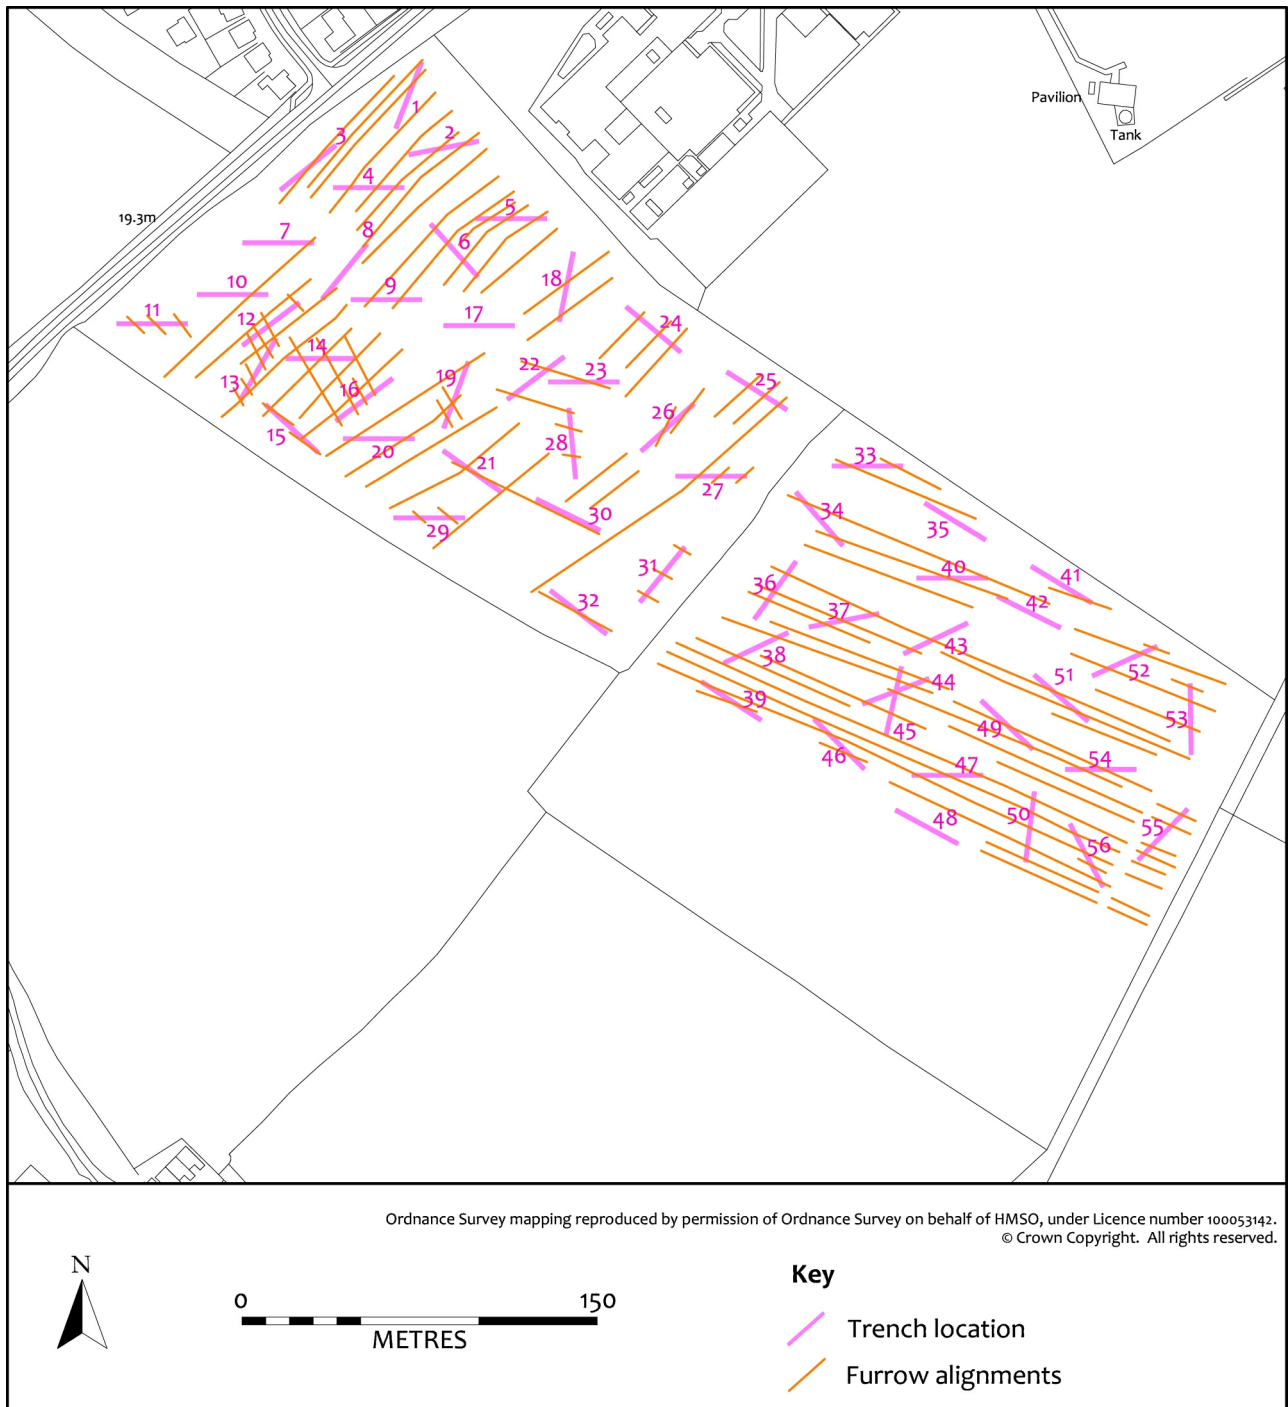

Figure 7. Location of furrow alignments identified in the evaluation.

3.2 Overburden

3.2.1 The proposed development area's character was a gently sloping pastoral field system, with the evaluation area divided into two by a field boundary. The topsoil/turf was a mid-dark grey fairly firm clay loam (1). The matrix contained modern debris including ceramics, plastic, slate, nails and hinges, as well as a varying degree of coal and fly ash. There was no visible topsoil/subsoil horizon, with the material lying directly over natural geology or furrow remnants. The topsoil varied in thickness across the site, but averaged between 0.3-0.35m.

Plate 2. View of cut [3] in Trench 12, looking northeast.

3.3 Geology

- 3.3.1 The natural geology beneath the evaluation area was observed to be Diamicton Till (**G1**) comprising banded clay with gravel deposits. Heavy plough scarring was noted cut into the clay, as were a number of furrows from the ridge and furrow field systems identified on the geophysical survey as well as a network of field drains. The depth of the geological horizon ranged from 8.94m OD to 18.159m OD.

3.4 Drainage

- 3.4.1 The majority of trenches revealed the presence of a network of field drains running at various angles and directions (see *Figure 6*). These field drains correspond to and account for the presence of linear anomalies on the geophysical survey.

3.5 Archaeology

- 3.5.1 **Furrows.** The geophysical survey identified two separate ridge and furrow field systems, with the western field containing a northeast-southwest alignment and the eastern field containing a northwest-southeast alignment. The evaluation suggested that the alignment in the eastern field originally continued into the western field, with evidence of potentially a third alignment in the western extent of the evaluation area aligned at a sharper northwest-southeast alignment. The northeast-southwest aligned furrows in the western field appear to be the potentially early 19th century in date. The fill of the furrows was a light brown/grey lightly silty sandy clay with inclusions of small stones, coal fragments and 19th century ceramic sherds. The fill was given a general context

identifier of (2), rather than produce separate identifiers for each furrow fill. One of the furrows in Trench 6 also produced a sherd of late 16th century pottery, likely to be background material. A similar fragment was also recovered from the southeast-northwest alignment of furrows in Trench 12. With no earlier background material recovered from the evaluation, this suggests the agricultural field systems are late medieval through to 19th century in date, with the northwest-southeast alignments pre-dating the southwest-northeast alignment. The plot of the furrow alignments can be seen in Figure 7.

3.5.2 **Trench 12:** A single linear feature was noted in Trench 12 (see Plate 2). This feature ran on a northeast-southwest alignment and cut two furrows. The cut [3] was truncated with a maximum depth of 0.10m and width of 0.5m existing. It was filled by brown-grey sandy loam (4) with inclusions of small stones, fly ash and coal waste. 15m of the cut was recorded across the trench, which was noted to be on exactly the same alignment as field drains observed to the north and south: as such it can be concluded that this was likely a drain or similar system that had been ploughed out.

3.5.3 **Trenches 1-11, 13-56:** No archaeological remains of interest were noted within these trenches, barring the aforementioned furrows and field drains. A summary of the depths and numbers of furrows/drains can be seen on Table 1.

4. DISCUSSION

Plate 59. Trenching underway

4.1 Overview

- 4.1.1 56 trenches were excavated totalling 3024m² or 4% of the overall evaluation area as stipulated in the agreed Written Scheme of Investigation. The trenches were excavated by a 14 tonne JCB with 1.8m wide toothless ditching bucket under constant archaeological supervision. Once excavated, the trenches were cleaned using hand tools and recorded before being backfilled.
- 4.1.2 COVID-19 restrictions were adhered to.

4.2 Discussion

- 4.2.1 The proposed development area's character was a gently sloping pastoral field system, with the evaluation area divided into two by a field boundary. The topsoil/turf contained modern debris including ceramics, plastic, slate, nails and hinges, as well as a varying degree of coal and fly ash. There was no visible topsoil/subsoil horizon, with the material lying directly over natural geology or furrow remnants. The topsoil varied in thickness across the site, but averaged between 0.3-0.35m.
- 4.2.2 The majority of trenches revealed the presence of a network of field drains running at various angles and directions. As well as the field drains, most of the trenches contained the remains of truncated furrows. The geophysical survey had identified two separate ridge and furrow field systems, with the western field containing a northeast-southwest alignment and the eastern field containing a northwest-southeast alignment. The evaluation suggested that the alignment in the eastern field originally continued into the western field, with evidence of potentially a third alignment in the western extent of the evaluation area aligned at a sharper northwest-southeast alignment. The northeast-southwest aligned furrows in the western field appear to be the potentially early 19th century in date. The fill of the furrows contained inclusions of small stones, coal fragments and 19th century ceramic sherds. One of the furrows in Trench 6 also produced a sherd of late 16th century pottery, likely to be background material. A similar fragment was also recovered from the southeast-northwest alignment of furrows in Trench 12. With no earlier background material recovered from the evaluation, this suggests the agricultural field systems

Plate 60. Trench 19, testing field drain cut

are late medieval through to 19th century in date, with the northwest-southeast alignments pre-dating the southwest-northeast alignment.

- 4.2.3 The natural geology beneath the evaluation area was observed to be Diamicton Till comprising banded clay with gravel deposits. The depth of the geological horizon ranged from 8.94m OD to 18.15m OD.
- 4.2.4 No archaeological remains of interest were observed within the evaluation area, with artefacts (with the exception of the two sherds of background 16th century pottery) dating from the Victorian period through to the late 20th century. The potential archaeological features noted on the geophysical survey can be explained through the presence of crossing furrow systems, the field drain network and pockets of coal and ash in the overburden.
