# Tree-Ring Analysis of Timbers from Chethams Library and School, Long Millgate, Manchester 

Ian Tyers

#### Abstract

Summary Chethams Library and School is located in the centre of Manchester. The building was founded in AD 1421 as the domestic premises of the priests college serving the adjacent parish church, which is now Manchester Cathedral. Following suppression of the college during the reign of Edward VI it was acquired by the Stanleys, Earls of Derby, and used as a residence. The building was confiscated during the civil war and it was acquired by the executors of Humphrey Chetham (d AD 1653) in AD 1654. It was converted into a school for poor boys and a public library using the Chethams bequest by AD 1656 and AD 1661 respectively. Both organisations continue to occupy this remarkable building.

Tree-ring sampling of parts of the structure was commissioned to inform repair decisions. The results indicate that almost all the accessible timber structure throughout the cloistral ranges includes fifteenth century material. The high levels of decoration have removed most of the sapwood and detailed differences in chronology have mostly proved impracticable to identify, although there are hints of differences in construction date between a number of areas. Two sixteenth century timbers have been identified in one area of the cloisters, perhaps indicating Stanley-era modifications.

# TREE-RING ANALYSIS OF TIMBERS FROM CHETHAMS LIBRARY AND SCHOOL, LONG MILLGATE, MANCHESTER 

## Introduction

This document is a technical archive report on the tree-ring analysis of oak timbers from Chethams Library and School, Long Millgate, Manchester, formerly Greater Manchester but now part of the Unitary Authority of Manchester (Figs 1 and 2; NGR SJ 839 989). It is beyond the dendrochronological brief to describe the buildings in detail or to undertake the production of detailed drawings.

Chethams School and Chethams Library effectively occupy parts of the same building. This was originally laid out as a series of priests lodgings (or sets) arranged around the cloistral garth, with a large hall to the east side of the cloister, and probably the senior lodgings on the south side. Most of the divisions on the south and west upper floors between the lodgings, presumably timber framed, are now gone and this provides the Library with a generally open aspect. The Library occupies the west and south sides of the cloistral range, and the School has most of the northern range, and the hall to the eastern side, as well as the extensive run of medieval buildings running east towards the gatehouse (Fig 3). The many later buildings within the complex are all school buildings. The three sides of the cloistral ranges and the hall are stone walled, with oak roofs that have similar truss designs and mostly similar mouldings. The roofs are of crown-post type with arched-braced collar/tiebeams and exceedingly short crown-posts (Fig 4), there are common rafter trusses with collars and simple bracing between the main trusses (Hartwell 2001). Most of the roofs appear to have been lath and plastered over at some stage, although this is now mostly removed. In the central area of the north cloistral range the present roof is a later restoration, in this case after a second world war incendiary explosion. There is some possibility that other parts of the roofs may be derived from other periods of reconstruction.

The ground-floor ceilings of the three cloistral ranges consists of a grid of large slightly cranked transverse moulded beams connecting with similarly moulded central joists and wall beams, all in oak. Here there is plain plasterwork, perhaps later in date, that hides the smaller joists except where there has been subsequent movement in the structure. The mouldings on the hall roof timbers and the ceiling beams of the cloistral ranges are similar. The southern ground-floor cloistral range ceiling has been thought to be of a slightly different date (Hartwell pers comm).

Around the garth side of the three cloistral ranges there is a ground-floor walkway, ceiled by a grid of oak slightly cranked moulded transverse beams, plain longitudinal joists, and moulded
wall beams. The mouldings of these are similar to both the hall and cloistral range mouldings. Throughout the walkway areas there are numerous signs of secondary insertions and repairs. There is a second floor to the walkway structure with a different roof line to the main building, however at no point within the complex is the roof of the walkway readily accessible and where it can be seen it is usually a recent replacement. Unfortunately in most areas it is boarded under and impossible to access. At two points, the north-west corner running west, and the south-west corner running south, the ground-floor inner walkway provides points of egress to the outside of the ranges. This is achieved by going through the ranges themselves at ground-floor level. In both cases, the structure visible in the corridor ceilings may structurally be either part of the cloistral ceiling or part of the walkway ceiling structure.

The complex is listed grade I. It should be noted that one of the school blocks is of the AD 1870s by Alfred Waterhouse. Waterhouse is known to have undertaken sympathetic restoration of the west cloistral range around the same period, further sympathetic restoration in AD 1883-95 by Heywood and Heywood also occurred. The degree of intervention into the original, or any other period, fabric at these times provided something of an unknown quantity for the sampling programme outlined here. A tree-ring dating programme of the timbers of the hall, and cloistral ranges, excluding the south west corner (Wardens lodgings and Audit room) and excluding the north east range down to and including the gatehouse (Buttery, Kitchen, Bakehouse, Dormitories, and Gatehouse) was requested by Marion Barter, English Heritage Historic Buildings Architect, to help inform future repair decisions.

## Methodology

The general methodology and working practises used at the Sheffield Dendrochronology Laboratory are described in English Heritage (1998). The methodology used for this building was as follows.

The sampling reported here was undertaken over a period of a week. A survey undertaken before this had identified those areas of the complex where oak timbers with suitable ring sequences for analysis survived. Those with more than 50 annual rings and some survival of the original sapwood and bark-edge were sought, although the level of decoration throughout has reduced the presence of both significantly. The dendrochronological sampling programme attempted to obtain cores from as broad a range of timbers, in terms of structural element types, scantling sizes, and carpentry features, as was possible within the terms of the request and with due regard to safety on site. The hall timbers were accessed with a scaffold tower kindly provided by and erected by the School. The cloistral ceiling and roof timbers, and the cloistral walkway ceiling timbers were all accessed by short ladders.

The most promising timbers were sampled using a 15 mm diameter corer attached to an electric drill. The cores were taken as closely as possible along the radius of the timbers so that the maximum number of rings could be obtained for subsequent analysis. The core holes were filled and stained throughout the normally accessible areas and the private apartments. The core holes in timbers in the book stack areas were left open to try to ensure they are well ventilated. The ring sequences in the cores were revealed by sanding.

Two additional timbers were collected and removed whole to the laboratory, these are two diamond pattern grilles, normally to be found suspended from nails in the cloister walkways. They are thought to be shutters for the cloister windows, although what period they are from is uncertain. Both are broken and have been mended with glues, screws and metal strips, on one or more occasions. One is complete, whilst the other has a corner missing. The ring sequences were recovered from the ends of the boards by direct measurement after removal of overlying grime and knifing the edge of the boards to reveal the ring sequences. Both have now been returned to the site, and are in store awaiting conservation treatment.

The complete sequences of growth rings in the samples that were selected for dating purposes were measured to an accuracy of 0.01 mm using a micro-computer based travelling stage (Tyers 1999a). The ring sequences were plotted onto semi-log graph paper to enable visual comparisons to be made between sequences. In addition a cross-correlation algorithm (Baillie and Pilcher 1973) was employed to search for positions where the ring sequences were highly correlated. These positions were checked visually using the graphs and, where these were satisfactory, new mean sequences were constructed from the synchronised sequences. The $t$ values reported below are derived from the original CROS algorithm (Baillie and Pilcher 1973). A $t$-value of 3.5 or over is usually indicative of a good match, although this is with the proviso that high $t$-values at the same relative or absolute position must be obtained from a range of independent sequences, and that these positions are supported by satisfactory visual matching.

All the measured sequences from this assemblage were compared with each other and any found to cross-match were combined to form a site master curve. These, and any remaining unmatched ring sequences were tested against a range of reference chronologies, using the same matching criteria: high $t$-values, replicated values against a range of chronologies at the same position, and satisfactory visual matching. Where such positions are found these provide calendar dates for the ring-sequence.

The tree-ring dates produced by this process initially only date the rings present in the timber. The interpretation of these dates relies upon the nature of the final rings in the sequence. If the sample ends in the heartwood of the original tree, a terminus post quem (tpq) for the felling of the tree is indicated by the date of the last ring plus the addition of the minimum expected number of sapwood rings which are missing. This tpq may be many decades prior to the real felling date. Where some of the outer sapwood or the heartwood/sapwood boundary survives on the sample, a felling date range can be calculated using the maximum and minimum number of sapwood rings likely to have been present. The sapwood estimates applied throughout this report are a minimum of 10 and maximum of 46 annual rings, where these figures indicate the $95 \%$ confidence limits of the range (Tyers 1998,a). These figures are applicable to oaks from England and Wales. Alternatively, if bark-edge survives, then a felling date can be directly utilised from the date of the last surviving ring. The dates obtained by the technique do not by themselves necessarily indicate the date of the structure from which they are derived. It is necessary to incorporate other specialist evidence concerning the re-use of timbers and the repairs of structures before the dendrochronological dates given here can be reliably interpreted as reflecting the construction date of phases within the structure.

A further important element of the tree-ring analysis of buildings and archaeological assemblages is the identification of 'same tree' groups within the sampled material. Inspection of timbers, both in buildings and archaeological sites, often suggests that the patterns of knots or branching in timbers are so similar that they appear to be derived from a single tree. Tree-ring analysis is often used to support these suggestions. The identification of 'same tree' groups is based on a combination of high levels of matching between samples, extremely similar longer term growth trends, and individual anatomical anomalies within the timbers. High $t$-values are not by themselves necessarily indicative of two series being derived from a single tree. Conversely low $t$-values do not necessarily exclude the possibility. It is the balance of a range of information that provides the evidence.

## Results

Forty seven core samples were obtained in February AD 2001. The sampling attempted to identify and core suitable timbers from the potentially different areas of the ranges and walkway ceilings in order to provide results that may indicate whether they were contemporary. It was apparent at the time of sampling that sapwood survival was poor in the building, principally because of the amount of deep carved decoration. It is thus self evident that small differences in date between different areas of the complex are unlikely to be identified by this analysis, instead major differences in the dates of construction or reconstruction are the main focus of the report. Overall 43 of these samples were analysed,
the remainder being either too short or too fragmented to analyse. In addition there are the two cloister shutter boards. The results are discussed initially for each area.

## Hall

Access to the timbers in this area was entirely by scaffold tower. This, fully extended, could reach the collars but not the purlins above that in the central bay. Reduced in height by a couple of tiers it provided access to the wall plates and lower arch braces against the walls. The presence of a large chandelier in the middle of the hall prevented access to timbers on the central truss (truss 3). A screen at the north end prevents access with the scaffold tower to the north wall truss (truss 1), the hall stage and above it the dais canopy likewise prevents tower access to the southern wall truss. During sampling no original truss numbers were identified that formed a sequence. The trusses were therefore assigned numbers from north to south. A total of sixteen timbers were selected as most suitable for sampling (Table 1). There was limited survival of sapwood throughout the decorated timbers in this part, although the need to produce curving arch braces from straighter trees yielded some signs of outermost rings at opposite ends of these timbers. The plain common rafters, braces, and upper purlins included several with clear survival of the heartwood/sapwood boundary but there was no survival of bark-edge in this area. The densely packed structure above the tiebeams meant that sampling locations could not always be optimal here. Several timbers with a different surface treatment and clearly visible band saw marks were thought to be fairly recent (nineteenth- or twentiethcentury repairs) and these were avoided for sampling purposes. The samples were numbered 1-16 inclusive. Two of the samples (numbers 4 and 13) when examined in the laboratory were rejected due to them having badly fragmented during sampling. In total therefore 14 samples were measured from this area and the resultant series were then compared with each other. Ten sequences were found that matched together to form one internally consistent group (Fig 5; Table 2). A 226-year interim site mean chronology was calculated, named CHET_H.

## Cloister walkway ceiling

Several timbers along the north side of the cloister walkway were sampled, along with a single timber from the south-side walkway. Both this latter, and one of the former, were thought to be potentially later modifications to the structure. Access in this area was undertaken with a short folding ladder. During sampling no original carpentry numbers were identified. The transverse beams were therefore used to define number bays around the cloister starting from the hall doorway. A total of seven timbers were selected as most suitable for sampling (Table 1). As with the hall there was limited survival of sapwood throughout the decorated timbers in this part, but as before the plainer timbers, in this area that is the joists, included several with clear survival of the heartwood/sapwood boundary and one with
survival of bark-edge. The proximity of the joists to the walls sometimes meant that sampling locations could not be optimal. In some instances the inability to fit equipment into the spaces precluded sampling in otherwise suitable timbers. As with other areas any timbers with a different surface treatment or clearly visible band saw marks were avoided for sampling purposes. The samples were numbered 17-22 inclusive and $\mathbf{2 8}$. One of the samples (number 17) when examined in the laboratory was rejected due to it having badly fragmented during sampling. In total therefore six samples were measured from these areas and the resultant series were then compared with each other and the CHET_H sequence. Four sequences were found that matched together to form one internally consistent group (Fig 5; Table 3). A 157year interim site mean chronology was calculated, named CHET_CW.

## Cloister range/walkway corridors

Several timbers from both the north-west walkway corridor ceiling and the south-west walkway corridor ceiling were sampled. Access in this area was again undertaken with a short folding ladder. During sampling no original carpentry numbers were identified. A total of five timbers were selected as most suitable for sampling (Table 1). As before there was limited survival of sapwood throughout the decorated timbers, but again the plainer joist timbers included some with clear survival of the heartwood/sapwood boundary. The awkward access to the closely packed joists meant that sampling locations could not always be optimal here. Several timbers with a different surface treatment and clearly visible band saw marks were thought to be fairly recent (nineteenth- or twentieth-century repairs) and these were avoided for sampling purposes. The samples were numbered 23-27 inclusive. All of the samples when examined in the laboratory were measured from this area. The resultant series were then compared with each other, and the two interim sequences constructed from the hall and cloister walkway areas. All five sequences were found to match together to form one internally consistent group (Fig 5; Table 4). A 170-year interim site mean chronology was calculated, named CHET_COR.

## Cloister north range roof

Timbers were sampled in the Headmistress's private first-floor accommodation. These rooms are derived from parts of four original priests sets on the north cloistral range. The eastern end of this is where the second world war incendiary device destroyed much of the original roof, and it is quite clear when examining this that this area has timbers with quite different surface treatments and toolmarks. At the west end of this range the roof timbers were readily accessible, although again no original carpentry numbers were identified. A total of four timbers originally in a single lodging were selected as most suitable for sampling (Table 1). As before there was limited survival of sapwood throughout these timbers. The presumably plainer rafters etc, were not accessible above a lath and plaster ceiling. The samples were
numbered 29-32 inclusive. All of the samples were measured from this area and the resultant series were then compared with each other and the three interim sequences. All four sequences were found to match together to form one internally consistent group (Fig 5; Table 5). A 190 -year interim site mean chronology was calculated, named CHET_NR.

## Cloister range west ceiling

Timbers in the book stacks under the west range of the Library were sampled. Access in this area was undertaken with a short folding ladder. During sampling no original carpentry numbers were identified. A total of six timbers originally within two different lodgings were selected as most suitable for sampling (Table 1). As before there was limited survival of sapwood throughout these timbers although the long lengths required clearly provided some difficulties for the original builders in this respect. Here the plainer timbers were not generally accessible. It is known Waterhouse was involved in enlarging windows in this area (Hartwell pers comm). This has evidently involved changing the dual purpose decorated wall beams/window lintels since they have different surface treatments and different surface tooling. These were avoided for sampling purposes. The samples were numbered 33-38 inclusive. All of the samples were measured from this area and the resultant series were then compared with each other and the previously constructed interim series. All the sequences were found to match together to form one internally consistent group (Fig 5; Table 6). A 163year interim site mean chronology was calculated, named CHET_WC.

## Cloister range south ceiling

Timbers in the controlled book stores under the south range of the Library were sampled. Access in this area was undertaken with a short folding ladder. During sampling no original carpentry numbers were identified. A total of seven timbers originally in a single lodging were selected as most suitable for sampling (Table 1). As before there was limited survival of sapwood throughout these timbers although here again the long lengths required and the deep carving clearly provided some difficulties for the original builders in this respect. Here the plainer timbers were not generally suitable nor accessible. The samples were numbered 41-47 inclusive. One of the samples (number 47) when examined in the laboratory was rejected due to it having badly fragmented during sampling. In total therefore six samples were measured from this area and the resultant series were then compared with each other and the previously constructed interim series. All these sequences were found to match together to form one internally consistent group (Fig 5; Table 7). A 158-year interim site mean chronology was calculated, named CHET_SC.

## 'Scriptorium' roof

The hall bay, immediately south of the chimney/inglenook was specified as an area for sampling. In the ground-floor section of this the mouldings of some timbers, presumably mostly hidden above the plaster work, are visible. However the grain direction and growth rates of these could not be reliably identified. Above this bay lies a room known as the 'scriptorium' although actually of unknown original purpose. It may not be contemporary with the room below, and the roof seems likely to have had later modifications since there are lines in the plaster apparently reflecting earlier arrangements. Two timbers were selected from here in order to investigate whether either the rather curious east side truss, or the current rafters were potentially original to the building (Table 1). As before there was limited survival of sapwood on these timbers. These samples were numbered 39 and $\mathbf{4 0}$. Both of the samples were measured and the resultant series were then compared with each other and the previously constructed interim series. Both sequences were found to match to the interim series in a highly consistent fashion (Fig 5; Table 8) A 107-year interim site mean chronology was calculated, named CHET_HB.

## Cloister Shutters

Both boards were cleaned and measured at both ends, the slow growing slightly tangential ring sequences were particularly awkward to recover due to the somewhat brittle nature of these timbers. The boards were numbered 48 and 49 (Fig 6; Table 1). The four series derived from both ends of both boards cross-match really well (Table 9), undoubtedly both boards are derived from a single long lived tree. A composite single series named $48+49$ was calculated from the series. This does not match the various interim site means produced.

## Dating the interim site means

The eight interim sequences, and the six remaining unmatched samples were then compared with each other. This identified that the seven structural interim series correlated (Table 10). A new composite series CHETHAM was constructed from these correlated interim sequences. This new series, and the residual unmatched material, was then compared with dated reference chronologies from throughout the British Isles and northern Europe. A single well correlated position was identified for the CHETHAM sequence. Table 11 shows some example correlations of the CHETHAM mean sequences at its identified dating position, AD 1185 - AD 1428 inclusive. Two of the unmatched samples, and the shutter sequence correlate consistently with later medieval series although they do not match each other especially well. Table 12 shows some example correlations for the two structural series at their identified dating positions. Table 13 shows some example correlations of the shutter sequence $48+49$ at its identified dating position. The remaining four series, all relatively short, failed to correlate with any reference data and remain undated by this analysis.

## Discussion

## The early fifteenth century.

The 244-year chronology CHETHAM is dated AD 1185 to 1428 inclusive. It was created from 37 timbers from the hall and cloistral ranges at Chethams. One of the cloistral walkway samples (sample 22) is definitely complete to bark-edge, in this case an incomplete ring for AD 1429 indicates felling occurred in the spring of that year. Ten other dated samples retain either incomplete sapwood or the identifiable heartwood/sapwood boundaries. The AD 1429 dating of a walkway timber suggests this area of the complex was built some eight years after the license to convert the parish church into a collegiate church was granted. This area was thus still apparently under construction after the death of the founding rector and lord of the manor (Thomas de la Warre d AD 1426). However the absence of surviving sapwood on most of the timbers has resulted in most of the sampled areas having felling date ranges that cover the period from $c$ AD 1410 (ie before the license) through to the AD 1440s (Fig 7). It is not suggested here that any of the extant structure predates the license in AD 1421, instead the lack of sapwood prevents dendrochronology from proving that it cannot predate the license. The combined felling date ranges for each area are sufficiently broad that precise interpretation of the sequence of construction of the complex is impossible to achieve reliably. The results do convincingly indicate that much of the structure remains intact from the foundation of the collegiate church. The one tentative indication of phasing of construction is derived from the south range ceiling which appears to predate the cloister walkway since the latest likely felling of sample 42 is AD 1424. This may indicate that the walkways were later than some part of the cloistral accommodation, or that the senior lodgings were amongst the earliest completed parts of the complex.

Observations during sampling revealed extensive and clear signs of warping of the timbers after being converted from the trunks into usable beams. Similarly the mouldings show characteristic distortions clearly due to warping after carving. Both these indicate the use of green timber throughout the fifteenth century framing of these ranges and implies the felling dates and felling date ranges identified are likely to be coterminous with the construction dates of these areas. Overall it is clear that construction dates for all areas in the second quarter of the fifteenth century is indicated by these results.

## Later timbers

Two later dated samples appear to indicate the first bay of the cloister walkway nearest the hall has been modified in the later sixteenth or early seventeenth centuries (Figs 6,8). The undated sample from a decorated wall plate from the hall (sample 16) shows some similarities in colour and growth rates to these two samples and may indicate all these timbers relate to
the otherwise undated insertion of the chimney and other modifications on the west side of the hall.

The two cloister shutters are of late seventeenth- or early eighteenth-century date. In strict terms they date from sometime after AD 1679 but since they are already quite long lived (235 years plus the missing centre and at least the missing sapwood), and they are quite broad for a single radius $(0.35 \mathrm{~m})$, it seems unlikely they have been cut from a significantly older or bigger tree. Assuming they are original to the building they are the only evidence currently obtained for works of the Chethams period.

## Conclusion

Analysis of a series of 47 cores from structural timbers in the Chethams cloistral ranges and hall has resulted in the production of estimated felling date ranges for a number of separate areas of the complex. These show that almost the entire structure retains significant fifteenthcentury structural elements. The presence of identified sixteenth- or seventeenth-century timbers in only one small area suggests the degree of reconstruction after firstly its dissolution and secondly after the civil war were not as extensive as had been thought, at least in these areas of the property. Timbers recognised as from the more recent repairs were excluded from the analysis. The tree-ring chronology is a well replicated sequence which appears to be a useful contribution to the regional data series. The high levels of correlation between samples from different areas as well as the consistent overall slow growth rates interspersed by periods of extremely slow growth appears to imply a limited range of woodland sources was used for the original construction of the complex. Two shutters are identified as late seventeenthcentury objects.

## Acknowledgements

The sampling and analysis programme was funded by English Heritage. Marian Barter, Alex Bayliss, and Peter Marshall all from English Heritage provided useful discussion. Clare Hartwell provided an incredible amount of useful information through her draft reports and her observations during sites visits. Her willingness to guide me through the complexities of the structure and the obscurities of its development have helped ensure the sampling has been aimed at the most useful timbers whenever practicable. Michael Powell, Fergus Wilde, and Anne Leslie from the Library all helped during the assessment visits and over the long week of sampling through their combined enthusiasm and deep mines of information, their coffee making, and their skills with the fire alarm systems proved invaluable. Dave Mulligan, Ged, and Eddy all helped with scaffold towers, keys, and other practical issues too numerous to mention. The School also generously provided use of accommodation on site which made some of the practical aspects of the work easier. The School Headmistress Mrs Moreland
kindly allowed access to her rooms in her absence, Mrs Woods, Domestic Services Manager, facilitated the use of on-site accommodation. Colin Jackson, Sheffield University Finance Department, and Cyril Barratt, Bursar from Chethams School, kindly liased over the issues of third party insurance cover in this building. Sue Stallibrass, English Heritage Regional Science Advisor currently based in Liverpool University, kindly came out to site to try to understand some of the practical issues involved in sampling timbers within buildings and to discuss the sort of information likely to be forthcoming. My colleague Cathy Groves provided useful discussion of the results and conclusions.

Figure 5 Bar diagram showing the chronological positions of the dated timbers from Chethams Library and School. The felling period for each sequence is also shown

Figure 6 The shutter samples 48 and 49 , both boards are approximately 690 mm high, 355 mm wide, and 15 mm thick. The grain pattern in 49 is highly distorted compared to 48 due to the presence of a large knot, this may have encouraged its subsequent breakage.
Curiously although both boards have clear marking out lines scribed on this face, both have been marked out with the same systematic inaccuracy (for example the left hand column of diamond cut-outs gets less complete down both the boards).

48

49

Figure 7 Summary of the results for each area of the complex.
Chethams Library and School

## Table 1

List of samples obtained from Chethams Library and School, Manchester, data from each core is listed in Appendix 1.

| Core Origin of core <br> No | Total <br> rings | Sapwood <br> rings | ARW <br> mm/year | Date of sequence | Felling period |
| :--- | :---: | :---: | :---: | :---: | :---: |
| HALL |  |  |  |  |  |
| $\mathbf{1}$ | Truss 4 west upper brace | $20+74+40$ | - | 1.04 | AD 1185-AD 1258 | after AD 1308

Table 1 (cont)

| $\begin{gathered} \hline \text { Core } \\ \text { No } \\ \hline \end{gathered}$ | Origin of core | Total rings | Sapwood rings | ARW $\mathrm{mm} /$ year | Date of sequence | Felling period |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | CLOISTER WALK - SOUTH |  |  |  |  |  |
| 28 | Western of paired beams | 111 | $\mathrm{h} / \mathrm{s}$ ? | 0.75 | AD 1291-AD 1401 | AD 1411-47? |
|  | CLOISTER RANGE - NORTH |  |  |  |  |  |
| 29 | Truss 2 north upper brace | 97 | - | 1.41 | AD 1211-AD 1307 | after AD 1317 |
| 30 | Truss 2 north lower brace | 125 | - | 1.24 | AD1265-AD 1389 | after AD 1399 |
| 31 | Truss 2 south upper brace | 135 | - | 1.19 | AD 1214-AD 1348 | after AD 1358 |
| 32 | South east stud/storey post | 139 | 4 | 0.88 | AD 1265-AD 1403 | AD 1409-45 |
|  | CLOISTER RANGE - WEST |  |  |  |  |  |
| 33 | Ceiling east-west beam | 131 | h/s | 1.80 | AD 1266-AD 1396 | AD 1406-42 |
| 34 | Ceiling north-south beam | 54 | - | 1.27 | AD 1262-AD 1315 | after AD 1325 |
| 35 | Ceiling north-south beam | 93 | - | 1.52 | AD 1238-AD 1330 | after AD 1340 |
| 36 | Ceiling east-west beam | 69 | h/s | 1.42 | AD 1332-AD 1400 | AD 1410-46 |
| 37 | Ceiling north-south beam | 54 | - | 2.49 | AD 1251-AD 1304 | after AD 1314 |
| 38 | Ceiling north wall plate | 93 | - | 1.52 | AD 1265-AD-1357- | after AD 1367 |
|  | HALL - 'Scriptorium' |  |  |  |  |  |
| 39 | East truss south vertical post | 73 | - | 1.47 | AD 1284-AD 1356 | after AD 1366 |
| 40 | Rafter south east corner | 99 | - | 1.57 | AD 1292-AD 1390 | after AD 1400 |
|  | CLOISTER RANGE - SOUTH |  |  |  |  |  |
| 41 | Ceiling north-south beam | 141 | - | 1.78 | AD 1247-AD 1387 | after AD 1397 |
| 42 | Ceiling south wall plate | 109 | $\mathrm{h} / \mathrm{s}$ | 0.94 | AD 1270-AD 1378 | AD 1388-1424 |
| 43 | Ceiling east-west beam | 118 | h/s | 1.20 | AD 1279-AD 1396 | AD 1406-42 |
| 44 | Ceiling east wall plate | 53 | - | 1.76 | AD 1339-AD 1391 | after AD 1401 |
| 45 | Ceiling north wall plate | 83 | - | 1.46 | AD 1259-AD 1341 | after AD 1351 |

| 47 | Ceiling south wall plate | - | - | - | Not measured | - |
|  | CLOISTER SHUTTERS |  |  |  |  |  |
| 48 | Shutter - complete | 233 | - | 1.46 | AD 1437-AD 1669 | after AD 1679 |
| 49 | Shutter - broken | 142 | - | 1.92 | AD 1435-AD 1576 | after AD 1586 |

## KEY

Total rings $=$ all measured rings, figures in italics indicate detached or un-measurable sections of the cores. Sapwood rings: $\mathrm{h} / \mathrm{s}$ heartwood/sapwood boundary, ?h/s possible heartwood/sapwood boundary, Bs bark spring felled. ARW = average ring width of the measured rings ( $\mathrm{mm} / \mathrm{year}$ )

[^0]:    Many CfA reports are interim reports which make available the results of specialist investigations in advance of full publication. They are not subject to external refereeing, and their conclusions may sometimes have to be modified in the light of archaeological information that was not available at the time of the investigation. Readers are therefore advised to consult the author before citing the report in any publication and to consult the final excavation report when available.
