Summary

A detailed gradiometer survey was conducted over land at Snarrows Sewage Treatment Works to River Trent Transfer Main, Leicestershire (between NGR 441918, 323985 and NGR 443255, 318676). The project was commissioned by Severn Trent Water with the aim of establishing the presence, or otherwise, and nature of detectable archaeological features in support of a planning application for the development of the site as a route for a effluent/settled storm transfer pipeline.

The site comprises arable and pasture fields located between Moor Lane, Tonge and Snarrows Road, Thringstone, covering an area of 15.9 ha. The geophysical survey was undertaken between 06 - 09 and 13 - 14 March 2023. The detailed gradiometer survey has been successful in detecting anomalies of possible archaeological and agricultural origin.

A possible ditched enclosure of unknown origin has been detected in the south of the site, within an area of ridge and furrow. A natural origin, such as a natural drainage feature, cannot however be ruled out.

Various anomalies representative of the past agricultural use of the land have been detected. Ridge and furrow cultivation dating mainly from the medieval period has been identified across the site. It is linked to the nearby settlements of Belton and Tonge, as well as Grace Dieu Priory. Several former field boundaries have also been identified which correspond with field boundaries seen in the OS 1st edition (1883) mapping.

In addition to this natural variation in the underlying deposits, drains, and various magnetic trends have been identified across the site. Areas of ferrous and magnetic disturbance have been detected and are associated with the edges and entrances to fields.

Acknowledgements

Wessex Archaeology would like to thank Severn Trent Water for commissioning the geophysical survey. The assistance of Deborah Goodale is gratefully acknowledged in this regard.

The fieldwork was undertaken by Filippo Carrozzo, Manasi Patil, Jo Instone-Brewer, Jack Trueman, and Phoebe Baker. Callum Jervis and Andrew Marke assisted in initial interpretation of the data. The majority of the geophysical data was processed, interpreted, and reported on by Lydia Jones. Lydia Jones prepared the illustrations. The geophysical work was quality controlled by Lydia Jones. The project was managed on behalf of Wessex Archaeology by Chris Breedon.

Snarrows Sewage Treatment Works to River Trent Transfer Main, Leicestershire

Detailed Gradiometer Survey Report

1 INTRODUCTION

1.1 **Project background**

1.1.1 Wessex Archaeology was commissioned by Severn Trent Water to carry out a geophysical survey at Snarrows Sewage Treatment Works to River Trent Transfer Main, Leicestershire (between NGR 441918 323985 and NGR 443255 318676) (**Figure 1**). The survey forms part of an ongoing programme of archaeological works being undertaken in support of a planning application for the route of a effluent/settled storm transfer pipeline.

1.2 Scope of document

1.2.1 This report presents a brief description of the methodology followed by the detailed survey results and the archaeological interpretation of the geophysical data.

1.3 The site

- 1.3.1 The site is located between Castle Donnington, 3.6 km to the north-east of the northern extremity of the site, and Coalville, 3.7 km to the south of the southern extremity of the site, in the county of Leicestershire.
- 1.3.2 The entire survey area comprises 15.9 ha of agricultural land utilised for arable crop and pasture.
- 1.3.3 The survey area has been split into two separate evaluation areas to better discuss the geographical and geological context (**Figure 1**).

Area 1 (LP_001 – 006)

- 1.3.4 The area covers LP_001 006 between Moor Lane, Tonge, DE73 8BB (NGR 441918 323985) and Mill Lane, LE12 9UJ (NGR 444239 321860). It is bounded to the north by the A453 and agricultural land, Mill Lane to the south, and the A453 (Mill Lane) and further agricultural land to the east and west. The area is crossed east west by the A42 and several smaller roads on various orientations.
- 1.3.5 The area varies in elevation from 54 m above Ordnance Datum (aOD) in LP_001 at the northern extent, up to 91 m aOD in LP_002, and 71 m aOD at LP_005, to 83 m aOD at LP_006.
- 1.3.6 The solid geology comprises mainly of Mudstone of the Gunthorpe Member with a small area of Siltstone Gunthorpe member in LP_002. A narrow band of Diseworth Sandstone is recorded close to the eastern boundary of LP_005. Superficial deposits consist mainly of Diamicton of the Thrussington Member, except for deposits of Head clay, silt, sand, and gravel at LP_001, and Diamicton of the Oadby Member at LP_006 (BGS 2023).
- 1.3.7 The soils underlying the site are likely to consist of stagnogleyic argillic brown earths of the 572c (Hodnet) association in the very north of the site at LP_001, argillic pelosols of the 431

(Worcester) association at LP_002, and stagnogley soils of the 711m (Salop) association in the south of the area. Soils derived from such geological parent material have been shown to produce magnetic contrasts acceptable for the detection of archaeological remains through magnetometer survey.

Area 2 (LP_007-017)

- 1.3.8 The area covers LP_007 017 between Mill Lane, LE12 9UJ (NGR 444191 321354) and Snarrows Road, Thringstone, LE67 8UR (NGR 443255 318676). It is bounded by Mill Lane to the north, Snarrows Road to the south, Gracedieu Lane to the south-east, and the village of Belton to the east. The area is bounded further by agricultural land to the north-east and west. Ashby Road runs east west through the north of the area.
- 1.3.9 The area varies in elevation from 76 m aOD at its northern extent to 85 m aOD at its southern boundary. The lowest elevation is recorded in LP_008, north-west of Belton, at 68 m aOD.
- 1.3.10 The solid geology comprises Mudstone of the Gunthorpe Member across the majority of the area with the exception of Sandstone of the Shepshed Sandstone Member at the southern extent of the site at LP_015 017. Diseworth Sandstone is recorded in the very north-west of LP_007 and a small area of Dolomitic Siltstone of the Gunthorpe Member is recorded at LP_014. Superficial deposits consist mainly of Diamicton of the Thrussington Member with small areas of mid-Pleistocene glaciofluvial deposits of sand and gravel (BGS 2023).
- 1.3.11 The soils underlying the site are likely to consist of stagnogleyic argillic brown earths of the 572g (Dunnington Heath) association and stagnogley soils of the 711m (Salop) association in the north of the area at LP_007 008, and stagnogleyic argillic brown earths of the 572g (Dunnington Heath) association further south at LP_009 14. The south of the area is likely to consist of argillic pelosols of the 431 (Worcester) association. Soils derived from such geological parent material have been shown to produce magnetic contrasts acceptable for the detection of archaeological remains through magnetometer survey.

2 ARCHAEOLOGICAL BACKGROUND

2.1 Introduction

2.1.1 The archaeological and historical background was assessed in a prior desk-based assessment (DBA) (Mott Macdonald 2022), which considered the recorded historic environment resource within a 500 m study area of the proposed development. The DBA used information from the Leicestershire Historic Environment Record (HER), the National Heritage List for England (NHLE) as well as information collected on a site visit. Additional sources of information are referenced, as appropriate. The findings of the DBA are summarised below.

2.2 Summary of the archaeological resource

- 2.2.1 Within the 500 m search area there are 12 designated heritage assets comprising 1 scheduled monument and 11 listed buildings.
- 2.2.2 Within the village of Belton, 260 m to the east of the site (LP_008) are the medieval Grade II* listed Church of St John the Baptist (NHLE 1074123), and various other post-medieval buildings including dwellings (NHLE 1074122, 1361361, 1361362, 1074121), a former vicarage (NHLE 1074124), a bakery (NHLE 1074120), a public house (NHLE 1361363), and a telephone kiosk (NHLE 1064283).

- 2.2.3 The scheduled monument of Grace Dieu Priory (NHLE 1012001) is located 240 m to the south of Area 2. The Augustinian Nunnery was founded between 1236 and 1242 and later converted into a Tudor mansion. It survives as extensive ruins of priory buildings (Grade II listed buildings NHLE 1074118) surrounded by a complex of earthworks including two ponds, a fishpond, boundary ditch, and wall.
- 2.2.4 A Grade II listed mile post (NHLE 1074119) is located 420 m south of the southern extent of the site on Ashby Road.

Prehistoric

2.2.5 A Mesolithic flint scatter was recorded during fieldwalking between 1994 – 1997 500 m north-east of LP_016. A Neolithic and Bronze Age lithic scatter was also recorded in the same area. An Iron Age enclosure has been identified via aerial photography 380 m east of LP_016. Undated cropmarks, located 400 m east of LP_006 and 420 m east of LP_005, suggest possible further prehistoric potential.

Romano-British

2.2.6 Immediately to the east of LP_003, the postulated route of a Roman Road is recorded. This is believed to link Watling Street, at Tamworth, to a crossing of the Trent, at Sawley. The alignment is suggested based on existing routes, a series of straight parish boundaries, and place names. Roman findspots are recorded in the vicinity of the site including pottery sherds 340 m to the east of LP_008. A find spot of brooches, coins, a spoon, and pottery is located 500 m to the east of LP_017.

Early medieval

2.2.7 Sherds of Anglo-Saxon pottery were discovered during a watching brief in 2008, 340 m to the east of LP_008. Just over 500 m from the northern extent of the site is the village of Tonge, which was recorded in the Domesday survey of 1086 as having 37 households.

Medieval

- 2.2.8 Analysis of LiDAR and observations during a site visit have detected extant, possibly medieval, ridge and furrow cultivation within LP_009 LP_014 and LP_001.
- 2.2.9 The village of Belton, 260 m to the east of the site, has a medieval settlement core, including the Grade II* church of St John the Baptist. A medieval market is also recorded in the village.
- 2.2.10 The village of Tonge, just over 500 m to the south-east of the northern extent of the site, developed during the medieval period. Historical mapping of the village in 1758 shows earthwork remains of the old village, such as farmsteads and a number of closes later cut by the Midlands Railway. A deer park is recorded as having been located 480 m to southwest of LP_002.

Post-medieval

2.2.11 Historical OS mapping shows the area to have been agricultural in nature and shows the landscape to have been an enclosed field system. Various farm buildings were built and are still in use in the landscape surrounding the site. The village of Belton expands slightly during this period. By 1696 most of the buildings at Grace Dieu Priory, 240 m to the south of the southern extent of the site, had been pulled down. Just to the south of the priory, quarrying was recorded on historical OS mapping during the 18th century. The Charnwood Forest Railway, opened in 1883, passes 440 m to the south-east of the southern extent of the site. The Midland Railway Ashby to Derby line opened during this period, 180 m to the west of the northern extent of the site.

Modern

2.2.12 The landscape has remained in agricultural use into the modern period, although removal of field boundaries has resulted in some larger fields. The A42 which runs east – west through the north of the area was built in 1989.

2.3 Recent investigations in the area

- 2.3.1 There have been various archaeological investigations within 500 m of the site. The most relevant and closest are discussed in this section.
- 2.3.2 Various investigations have been undertaken at Grace Dieu Priory, located 240 m to the south of the southern extent of the site. These include building survey, fieldwalking, research prior to consolidating the ruins, a watching brief, and trial trenching.
- 2.3.3 A watching brief was undertaken in 2000, 400 m to the south of LP_001 near the village of Tonge. Evidence for early road surfaces and post-medieval activity was recorded.
- 2.3.4 A watching brief in 2007, conducted 380 m to the east of LP_008 in Belton, discovered a pit containing Saxon pottery. Roman, Saxon, and medieval pottery, as well as a Bronze Age scraper, were all recovered from the topsoil.
- 2.3.5 A DBA was conducted in 2008 which identified medieval village earthworks 50 m to the south-west of LP_001, on the opposite side of Moor Lane.
- 2.3.6 A magnetometer survey was undertaken 270 m to the north-west of the southern extent of the site. Most of the anomalies detected were agricultural in origin, such as ridge and furrow.
- 2.3.7 A watching brief in 2014, conducted 385 m to the east of LP_008 in Belton, discovered an articulated skeleton and charnel in the subsoil.

3 METHODOLOGY

3.1 Introduction

- 3.1.1 The geophysical survey was undertaken by Wessex Archaeology's in-house geophysics team between 06 09 & 13 14 March 2023. Field conditions at the time of the survey were mixed throughout, with heavy snow on 09 March. An overall coverage of 15.6 ha was achieved. A total of 0.4 ha was unsurveyed as LP_015 was inaccessible due to electric fencing and there were deep ruts in LP_002.
- 3.1.2 The methods and standards employed throughout the geophysical survey conform to that set out in the Written Scheme of Investigation (WSI) (Wessex Archaeology 2023), as well as to current best practice, and guidance outlined by the Chartered Institute for Archaeologists' (ClfA 2014) and European Archaeologiae Consilium (Schmidt *et al.* 2015).

3.2 Aims and objectives

- 3.2.1 The aims of the survey comprise the following:
 - To determine, as far as is reasonably possible, the nature of the detectable archaeological resource within a specified area using appropriate methods and practices; and
 - To inform either the scope and nature of any further archaeological work that may be required; or the formation of a mitigation strategy (to offset the impact of the development on the archaeological resource); or a management strategy.

- 3.2.2 In order to achieve the above aims, the objectives of the geophysical survey are:
 - To conduct a geophysical survey covering as much of the specified area as possible, allowing for on-site obstructions;
 - To clarify the presence/absence of anomalies of archaeological potential; and
 - Where possible, to determine the general nature of any anomalies of archaeological potential.

3.3 Fieldwork methodology

- 3.3.1 The cart-based gradiometer system used a Leica Captivate RTK GNSS instrument, which receives corrections from a network of reference stations operated by the Ordnance Survey (OS) and Leica Geosystems. Such instruments allow positions to be determined with a precision of 0.02 m in real-time and therefore exceeds European Archaeologiae Consilium recommendations (Schmidt *et al.* 2015).
- 3.3.2 The detailed gradiometer survey was conducted using four SenSys FGM650/3 magnetic gradiometers fixed horizontally 1 m apart on a non-magnetic cart with an effective sensitivity of 0.03 nT.

3.4 Data processing

- 3.4.1 Data from the survey were subjected to minimal correction processes. These comprise a 'Destripe' function (±5 nT thresholds), applied to correct for any variation between the sensors, and an interpolation used to grid the data and discard overlaps where transects have been collected too close together.
- 3.4.2 Further details of the geophysical and survey equipment, methods and processing are described in **Appendix 1**.

4 GEOPHYSICAL SURVEY RESULTS AND INTERPRETATION

4.1 Introduction

- 4.1.1 The detailed gradiometer survey has identified magnetic anomalies across the site, including medieval ridge and furrow, possible archaeological features, old field boundaries along with variations in the underlying natural deposits of the site. Drains and ferrous anomalies have also been identified. Results are presented as a series of greyscale plots (Fig. 4, 6, 8, 10, 12, 14, 16, 18) and archaeological interpretations (Fig. 5, 7, 9, 11, 13, 15, 17, 19) at a scale of 1:2000. The data are displayed at -2 nT (white) to +3 nT (black) for the greyscale image.
- 4.1.2 The interpretation of the datasets highlights the presence of potential archaeological anomalies, ferrous responses, burnt or fired objects, and magnetic trends (Fig. 5, 7, 9, 11, 13, 15, 17, 19). Full definitions of the interpretation terms used in this report are provided in Appendix 2.
- 4.1.3 Numerous ferrous anomalies are visible throughout the dataset. These are presumed to be modern in provenance and are not referred to, unless considered relevant to the archaeological interpretation.
- 4.1.4 It should be noted that small, weakly magnetised features may produce responses that are below the detection threshold of magnetometers. It may therefore be the case that more archaeological features may be present than have been identified through geophysical survey.

4.1.5 Gradiometer survey may not detect all services present on site. This report and accompanying illustrations should not be used as the sole source for service locations and appropriate equipment (e.g., CAT and Genny) should be used to confirm the location of buried services before any trenches are opened on site.

4.2 Gradiometer survey results and interpretation

- 4.2.1 A weak positive sub-rectilinear anomaly has been identified in LP_014 at **4000** (**Figure 17**). It covers an area of 31 m x 25 m and varies between 0.8 4 m in width. It is 'F-shaped' in form and oriented north-east to south-west. It is located within an area of medieval ridge and furrow and two of its lengths are oriented roughly in line with this. This combined with its broad morphology and weak magnetic signal indicates it may be a natural drainage feature. It is however possible that the anomaly is a group of ditches that combine to form an enclosure of unknown origin.
- 4.2.2 Linear anomalies spaced between 5 m 9 m have been detected across the site on various orientations (**Fig. 5, 7, 9, 11, 13, 15, 17, 19**). They are typical of ridge and furrow cultivation dating from the medieval and post-medieval periods. Those in LP_001 & LP_009 13 are particularly strong and have been detected previously in LiDAR as extant features. In LP_009 14 the ridge and furrow is visible as extant features. In LP_002, LP_004, and LP_007 the anomalies are weaker and less easy to define and may date from the medieval post-medieval period. However, where the anomalies are stronger and morphology clearer (LP001, LP_006 & LP_009-016) a more confident date of medieval can be assigned due to the curved form of the anomalies. The anomalies are within the agricultural lands surrounding the medieval centres of Tonge, Belton, and Grace Dieu Priory.
- 4.2.3 A strong linear dipolar anomaly measuring 58 m in length and 2 5 m in width has been detected crossing LP_001 at 4001 (Figure 5), oriented east west. A parallel positive linear anomaly has been detected 53 m to the south of 4001 at 4002. The anomaly is 1.2 m wide and 21 m in length (Figure 5). Both anomalies correspond with field boundaries mapped in the First Edition OS mapping from 1885 (Leicestershire Sheet IX, S.E), and are still visible on the OS mapping from 1967 (Derbyshire Leicestershire, Sheet SL 42 SW). Another strong linear dipolar anomaly at 4003 (Figure 19) measuring 54 m long and 1.2 9 m wide has been detected crossing LP_016, north-west to south-east. A positive linear anomaly has been detected 180 m to the south-west at 4004 (Figure 19). It measures 144 m long by 1.4 m wide and crosses LP_017 on a south-west to north-east orientation. Both anomalies correspond with field boundaries depicted on the First Edition OS mapping from 1883 (Leicestershire Sheet XVI.8) and are still depicted on the OS mapping from 1967 (Leicestershire, Sheet SK 41 NW).
- 4.2.4 A weak amorphous band of enhanced response at **4005** (**Figures 9 & 11**) has been detected crossing LP_003 on a north-east to south-west orientation. Given its morphology, location on a slope, and weak signal it is considered likely to be natural variations in the underlying deposits.
- 4.2.5 Various narrow weak positive and negative anomalies have been detected across the site. These are likely representative of the site's agricultural past in the form of cultivation and modern drainage.
- 4.2.6 An area of magnetic disturbance has been detected in LP_005 at **4006** (**Figure 11**). It is located at the bottom of a slope and a fired clay drain is seen running into it from the west. It is likely that this is an area that water drains into and as a result has become more disturbed.

5 DISCUSSION

- 5.1.1 The detailed gradiometer survey has been successful in detecting anomalies of possible archaeological and agricultural origin.
- 5.1.2 A possible ditched enclosure of unknown origin has been detected in the south of the site, within an area of ridge and furrow. A more natural origin, such as a natural drainage feature, cannot however be ruled out.
- 5.1.3 Various anomalies representative of the past agricultural use of the land have been detected. Ridge and furrow cultivation dating mainly from the medieval period has been identified across the site. They are linked to the nearby medieval settlements including the villages of Belton and Tonge, as well as Grace Dieu Priory. Several former field boundaries have also been identified which correspond with field boundaries seen in the OS 1st edition (1883) mapping.
- 5.1.4 In addition to this natural variation in the underlying deposits, drains, and various magnetic trends have been identified across the site. Areas of ferrous and magnetic disturbance have been detected and are associated with the edges and entrances to fields.

APPENDICES

Appendix 1 Survey equipment and data processing

Survey methods and equipment

The magnetic data for this project were acquired using a non-magnetic cart fitted with four SenSys FGM650/3 magnetic gradiometers. The instrument has four sensor assemblies fixed horizontally 1 m apart allowing four traverses to be recorded simultaneously. Each sensor contains two fluxgate magnetometers arranged vertically with a 0.6 m separation and measures the difference between the vertical components of the total magnetic field within each sensor array. This arrangement of magnetometers suppresses any diurnal or low frequency effects.

The gradiometers have an effective resolution of $\pm 8 \ \mu T$ over $\pm 1000 \ nT$ range. All of the data were then relayed to a CS35 tablet, running the MONMX program, which is used to record the survey data from the array of FMG650/3 probes at a rate of 20 Hz. The program also receives measurements from a GPS system, which is fixed to the cart at a measured distance from the sensors, providing real time locational data for each data point.

The cart-based system relies upon accurate GPS location data which is collected using a Carlson BRX7 system. This receives corrections from a network of reference stations operated by the Ordnance Survey, allowing positions to be determined with a precision of 0.02m in real-time and therefore exceed the level of accuracy recommended by European Archaeologiae Consilium recommendations (Schmidt *et al.* 2015) for geophysical surveys.

Post-processing

The magnetic data collected during the survey is downloaded from the system for processing and analysis using both commercial and in-house software. This software allows for both the data and the images to be processed in order to enhance the results for analysis; however, it should be noted that minimal data processing is conducted so as not to distort the anomalies.

Typical data and image processing steps may include:

- GPS DeStripe Determines the median of each transect and then subtracts that value from each datapoint in the transect within the defined window. May be used to remove the striping effect seen within a survey caused by directional effects, drift, etc.
- Discard Overlaps Intended to eliminate a track(s) that have been collected too close to one another. Without this, the results of the interpolation process can be distorted as it tries to accommodate very close points with potentially differing values.
- GPS Base Interpolation Sets the X & Y interval of the interpolated data and the track radius (area around each datapoint that is included in the interpolated result).

Typical displays of the data used during processing and analysis:

• Greyscale – Presents the data in plan view using a greyscale to indicate the relative strength of the signal at each measurement point. These plots can be produced in colour to highlight certain features but generally greyscale plots are used during analysis of the data.

Appendix 2 Geophysical interpretation

The interpretation methodology used by Wessex Archaeology separates the anomalies into four main categories: archaeological, modern, agricultural, and uncertain origin/geological.

The archaeological category is used for features when the form, nature and pattern of the anomaly are indicative of archaeological material. Further sources of information such as aerial photographs may also have been incorporated in providing the final interpretation. This category is further subdivided into three groups, implying a decreasing level of confidence:

- Archaeology used when there is a clear geophysical response and anthropogenic pattern.
- Possible archaeology used for features which give a response, but which form no discernible pattern or trend.

The modern category is used for anomalies that are presumed to be relatively modern in date:

- Ferrous used for responses caused by ferrous material. These anomalies are likely to be of modern origin.
- Modern service used for responses considered relating to cables and pipes; most are composed of ferrous/ceramic material although services made from non-magnetic material can sometimes be observed.

The agricultural category is used for the following:

- Former field boundaries used for ditch sections that correspond to the position of boundaries marked on earlier mapping.
- Ridge and furrow used for broad and diffuse linear anomalies that are considered to indicate areas of former ridge and furrow.
- Ploughing used for well-defined narrow linear responses, usually aligned parallel to existing field boundaries.
- Drainage used to define the course of ceramic field drains that are visible in the data as a series of repeating bipolar (black and white) responses.

The uncertain origin/geological category is used for features when the form, nature and pattern of the anomaly are not sufficient to warrant a classification as an archaeological feature. This category is further sub-divided into:

- Increased magnetic response used for areas dominated by indistinct anomalies which may have some archaeological potential.
- Trend used for low amplitude or indistinct linear anomalies.
- Superficial geology used for diffuse edged spreads considered to relate to shallow geological deposits. They can be distinguished as areas of positive, negative, or broad bipolar (positive and negative) anomalies.

Appendix 3 OASIS form

Project Details:

Project name		Snarrows Sewage Treatment Works to River Trent Transfer Main, Leicestershire					
Type of project		Detailed gradiometer survey					
Project description		The detailed gradiometer survey has been successful in detecting anomalies of possible archaeological and agricultural origin. A possible ditched enclosure of unknown origin has been detected in the south of the site, within an area of ridge and furrow. A more natural origin, such as a natural drainage feature, cannot however be ruled out. Various anomalies representative of the past agricultural use of the land have been detected. Ridge and furrow cultivation dating mainly from the medieval period has been identified across the site and are linked to the nearby settlements with a medieval origin including the villages of Belton and Tonge, as well as Grace Dieu Priory. Several former field boundaries have also been identified which correspond with field boundaries seen in the OS 1st edition (1883) mapping. In addition to this natural variation in the underlying deposits, drains and various magnetic trends have been identified across the site. Areas of ferrous and magnetic disturbance have been detected and are associated with the edges and entrances to fields.
