SUMMARY (non technical)

The Museum of London Archaeology Service and Pre-Construct Archaeology (MoLAS-PCA) were commissioned by the Olympic Delivery Authority to analyse and record the waterways in and around the Olympic development site in Stratford, and the standing structures associated with them. The waterways and structures were to be removed or altered in order to redevelop the site, and the archaeological investigation and a subsequent report were required as a condition of planning consent for the redevelopment. The investigation of the structures took place periodically from January 2007 to January 2008.

The waterways within the Olympic development site, comprising the River Lea, the Lea Navigation (Hackney Cut), the Waterworks River, the City Mill River, the Bow Back River, the Pudding Mill River, the Channelsea River and Henniker's and Potter's Ditches, were recorded, researched and analysed. A number of waterways-related built structures were also investigated as part of this exercise, and comprised a length of stone and brick riverbank wall on the west bank of the River Lea; Marshgate Lane Locks, Pudding Mill Lock and Old Ford Lock; Old Ford Lock Houses, and a pedestrian footbridge over the City Mill River.

The oldest structural remains date to the improvement schemes of the 1850s, which upgraded both medieval millstreams and natural rivers and created a single controlling body for the Lea Valley waterways, the Lea Conservancy Board. Before the creation of the Board, many stretches of the waterways were controlled by mill owners, who often did very little in the way of upkeep. The Board saw to it that the new waterways were wider and deeper than their predecessors, and introduced a lock-controlled toll system. The improvement schemes were closely linked to canal construction which facilitated the interlinking of major manufacturing centres across the country. This allowed heavy or bulky goods to be transported along faster, more reliable routes than the previous coastal and road courses. The River Lea and the Lea Navigation led straight from the Midlands to the mouth of the River Thames, making them and the associated waterways very useful transport routes.

The waterways became invaluable throughout the mid to late nineteenth century both as sources of water and transportation routes, and enabled several developments within the chemical, electrical, petroleum, and steel industries. The optimal conditions for manufacture in Stratford attracted these industries, creating an area which was both heavily industrialised and heavily polluted. The promise of work with these newly established industries attracted many people to the area, resulting in a significant increase in the population.

By the 1920s the backwaters of Stratford had become a constant source of complaint due to the pollution caused both by industrial effluent and drainage from sewage works into the rivers.

The 20th century brought competition for goods transportation from road haulage, and only the most commercially viable canals in the UK survived until the Second World War, among them the River Lea and Lea Navigation. After the war, decline of trade on all remaining canals was rapid, and by the mid-1960s only a token traffic was left, even on the widest and most industrialised waterways.

Britain's canal network, together with its surviving mill buildings, is one of the most enduring features of the early Industrial Revolution to be seen today. Its relative neglect after its fall into obsolescence has served to preserve it. The topography of the Stratford back rivers area assisted locally in this process, as the poor accessibility and marshy

nature of the land hampered development and alteration of the historic waterways structures. Many historic riverside buildings survive, particularly around the Old Ford Locks portion of the Lea Navigation, and historic features survive in the banking of the watercourses and along their towpaths.

Plate 13 View of East London rail bridge spanning the Lea Navigation, looking north: OL-01207	485
Plate 14 View of White Post Lane bridge spanning the Lea Navigation, looking south: OL-01207	485
Plate 15 View of Lea Navigation's east bank showing Larsen camp sheeting with metal bracketing and cobbled capping: OL-01207	486
Plate 16 View of first tipping wharf on eastern bank of the Lea Navigation, looking south-east: OL-01207	486
Plate 17 View of pedestrian bridge spanning the River Lea towards Manor Garden Allotments, looking east: OL-01207	487
Plate 18 View of pedestrian bridge spanning the River Lea, south-east of Old Ford Locks, looking north-east: OL-01207	488
Plate 19 View of Greenway bridge spanning the River Lea with sewage pipes on foreground, looking north-west: OL-01207	488
Plate 20 View of wattling on the west bank of the River Lea, looking west: OL-01207489	
Plate 21 View of the east bank of the River Lea showing imprints of timber shuttering and sockets for mooring rings, looking south-west: OL-01207	489
Plate 22 View of Henniker's Ditch, looking east: OL-02007	490
Plate 23 View of culverted junction between Henniker's and Potter's Ditches, looking north-northwest: OL-02007	490
Plate 24 View of curve of Potter's Ditch with timber revetment, looking south-east: OL-02007	491
Plate 25 View of Channelsea River towards Potter's Ditch, looking north-east: OL- 02007	492

Plate 26 View of City Mill River footbridge with Marshgate Lane road bridge in background, looking north-east: OL-03507	493
Plate 27 View of west bank of City Mill River with row of drainage holes immediately above waterline, looking west: OL-01207	493
Plate 28 View of eastern concrete bank of City Mill River with timber pull-up piles, looking south-east: OL-01207	494
Plate 29 View of mooring area between GNER bridge and Northern Outfall Sewer bridge, City Mill River, looking south-east: OL-01207	494
Plate 30 View of disused portion of Marshgate Lane Lock, City Mill River, looking east: OL-07407	495
Plate 31 View of southern tip of Marshgate Lane Lock and island, City Mill River, looking north-east: OL-07407	495
Plate 32 View of Blaker Road bridge spanning Bow Back River, looking north-east: OL-01207	496
Plate 33 View of Pudding Mill River footbridge spanning the junction of Pudding Mill River and the River Lea, looking north-west: OL-01207	496
Plate 34 View of northern side of Pudding Mill River footbridge spanning the River Lea, looking south-west: OL-01207	497
Plate 35 View of modern timber cofferdam on the Pudding Mill River, looking north-east: OL-01207	498
Plate 36 View of tyre dumping covering the east bank of the Pudding Mill River, looking south: OL-01207	499
Plate 37 View of concrete pile west bank of Pudding Mill River, looking south-west: OL-01207	499
Plate 38 View of modern timber bridge spanning the Pudding Mill River, looking south-east: OL-01207	500
Plate 39 View of concrete platform and banking on Pudding Mill River, looking south-west: OL-01207	500
Plate 40 View of the Waterworks River from Marshgate Lane road bridge, looking south-east: OL-01207	501
Plate 41 Oblique view of south elevation of Old Ford Lock Houses, looking north-northeast: OL-07307	501
Plate 42 View of three of the original ceramic roof finials, Old Ford Lock Houses, looking north-east: OL-07307	502
Plate 43 View of north elevation of Old Ford Lock Houses, looking south-east: OL-07307	502
Plate 44 View of west elevation of Old Ford Lock Houses with Old Ford Locks in foreground, looking east: OL-07307	503
Plate 45 View of south garden of Old Ford Lock Houses, looking north: OL-07307	503
Plate 46 Oblique view of west elevation of stables relating to the Old Ford Lock Houses, looking south-east: OL-07307	504
Plate 47 View of central island of Old Ford Locks with clough in foreground, looking north-west: OL-05007	504
Plate 48 View of weir on west bank of Old Ford Lock, with timber guard posts, looking west: OL-05007	505
Plate 49 Detailed view of navigation lamp on northern tip of Old Ford Locks dolphin, looking north: OL-05007	505
Plate 50 View of dolphin at north tip of central lock island, with mooring bollard in foreground looking north: OL-05007	506
Plate 51 View of central island of Old Ford Locks, showing control booth, looking north: OL-05007	506

Plate 52 View of east wall in east chamber of Old Ford Locks, showing brick bond pattern, looking east: OL-05007	507
Plate 53 Detailed view of mechanism and hinge of the west chamber's south gate, Old Ford Locks: OL-05007	508
Plate 54 View of mooring hook set into east wall of east chamber, Old Ford Locks, looking east: OL-05007	509
Plate 55 View of ladder set into the recess on the east wall of the east chamber, Old Ford Locks, looking east: OL-05007	510
Plate 56 View of stock groove on east chamber, Old Ford Locks, looking west: OL- 05007	511
Plate 57 View of south gate in west chamber, Old Ford Locks, looking west-northwest: OL-05007	512
Plate 58 View of south end of Old Ford Locks showing footbridge, lock gate and building fabric: OL-05007	512
Plate 59 View of Pudding Mill Lock, showing eastern towpath and footbridge in background, looking south-west: OL-05407	513
Plate 60 View of brick pier and east wing wall, Pudding Mill Lock, looking north: OL-05407	514
Plate 61 Detailed view of damaged eastern wing wall with metal mooring post, Pudding Mill River, looking north-northwest: OL-05407	515
Plate 62 View of metal fencing on east side of Pudding Mill Lock, looking south: OL-05407	516
Plate 63 View of lock gate recess on east side of central island, Pudding Mill Lock, looking north-west: OL-05407	517
Plate 64 View of Marshgate Lane Lock, looking south-west: OL-07407	518
Plate 65 View of Marshgate Lane Lock House, looking south-west: OL-07407	519
Plate 66 View of south gate of Marshgate Lane Lock, looking south-west: OL-07407520	
Plate 67 View of stone and brick riverbank wall, on west bank of River Lea, looking south: OL-07207	520
Plate 68 View of possible wharf entrance, stone and brick riverbank wall, looking south-west: OL-07207	521
Plate 69 View of continuation of stone and brick riverbank wall, looking west- southwest: OL-07207	521
Plate 70 View of stone and brick riverbank wall showing building fabric, looking north-west: OL-07207	522
Plate 71 View of Carpenter's Lock with City Mill River Footbridge in the background, looking south-southeast: OL-03007	522
Plate 72 View of south end of Carpenter's Lock, looking north: OL-03007	523
Plate 73 View of north gates of Carpenter's Lock, looking north-northwest: OL-03007523	
Plate 74 View of original lock mechanisms, Carpenter's Lock, looking east: OL-03007	524
Plate 75 View of ramp with granite risers on the east bank of the River Lea, Carpenter's Lock, looking south-west: OL-03007	525
Plate 76 View of modern tide gate with associated machinery, Carpenter's Lock, looking north-east: OL-03007	525
Plate 77 View of Thames Water sludge mains, immediately south of Carpenter's Lock, looking west: OL-03007	526
Plate 78 View of north end of Carpenter's Lock, looking south: OL-03007	527
Plate 79 Detailed view of junction between steel panel and lattice on north side of City Mill River Footbridge, looking north: OL-03507	528
Plate 80 Detailed view of layered steel panels on northern side of City Mill River Footbridge, looking north-west: OL-03507	529

Plate 81 View of northern side of City Mill River Footbridge and anchorage in concrete wall, looking north-east: OL-03507	530
Plate 82 Detailed view of handrail at the south side of the eastern end of the City Mill River Footbridge, looking south: OL-03507	531
Plate 83 Detailed view showing granite set risers and inset open ceramic drainpipes, City Mill River Footbridge, looking north-east: OL-03507	531

1 Introduction

1.1 Site background

The waterways and built heritage structures discussed in this report are located in the Lower Lea Valley (Figures 1-10). The River Lea flows through the southern stretch of the valley via a series of canalised and culverted channels, commonly referred to as the Stratford or Bow Back Rivers.

The east bank of the Lea Navigation (Hackney Cut), above Old Ford Locks, forms the borough boundary between Tower Hamlets, Newham and Hackney. Below Old Ford Locks, the Lea Navigation converges with the southern stretch of the River Lea. The River Lea and Lea Navigation were surveyed from their entry into the development area at the north (beneath the Eastway for the River Lea; beneath the Eastway at the Eastway Road Bridge for the Lea Navigation) to the exit of the River Lea at the south (beneath the Great Eastern Railway).

The Pudding Mill River is located north-east of the River Lea's junction with the Lea Navigation, extending a short distance south-west from the east bank of the Lea.

The City Mill River effectively flows under the Great Eastern Railway to converge with the Waterworks River which marks its end and the beginning of the Bow Back River, which flows southwards.

The Waterworks River flows under the Great Eastern Railway line.

The southern extent of the Channelsea River flows has been culverted and emerges near the Abbey Mills Pumping Station and then flows southwards.

A number of desk-top *Archaeological and Built Heritage impact assessments* were previously prepared by MoLAS-PCA, which cover the individual areas (Planning Delivery Zones (PDZs)) into which the Olympic Park was split for planning purposes. The area of each of the nine individual PDZs covers land that incorporates watercourses (and associated features) covered in this report, whether in detail or in general (i.e. as contextualising material). Therefore the nine PDZ assessments are relevant here. These assessments were written on a PDZ by PDZ basis: Planning Delivery Zones 1, 2, 3, 4, 5, 6, 7, 8 and 15 (MoLAS-PCA 2007a, 2007b, 2007c, 2007d, 2007e, 2007f, 2007g, 2007h & 2007i).

These documents should be referred to for information on the natural geology, archaeological and historical background of the site, and the initial assessment of its archaeological potential.

No previous description or investigation of the standing structures is known, with the exception of information contained within the document noted above. An assessment of the Waterways has previously been undertaken by MoLAS-PCA (MoLAS-PCA 2006), the results of which informed this recording exercise.

Overall, the waterways within the Olympic Park had been assigned one overarching site code: OL-01207 (NGR NW corner: 53692 18506; NE corner: 53768 18600; SW corner: 53756 18332; SE corner: 53880 18468) (Figure 1).

Within the complex of waterways, and also within these limits, a number of individual features were recorded/surveyed and assigned their own site codes. Each of these, discussed with their site codes here, was identified as being of significance in the relevant PDZ assessments (MoLAS-PCA 2007a, 2007b, 2007c, 2007d, 2007e, 2007f, 2007g, 2007h &

2007i), and therefore meriting recording. The site codes, allocated by the London Archaeology Archive Resource Centre (LAARC), provide the means by which the records are indexed and archived.

All these structures form part of the planning applications for the Olympic and Paralympic Games and Legacy Facilities in the London Boroughs of Newham, Tower Hamlets, Hackney, and Waltham Forest.

The location, OS grid references and site codes for each structure are as follows (NB – they are listed here in ascending numerical order of their site codes: elsewhere in this report they are discussed in order of geographical confluence, with relevant site code references):

1.1.1 OL-02007: Henniker's and Potter's Ditches

Located in PDZ6, these join the Channelsea River (Figure 3). OL-02007 was known for reference in the project as BH86. The Museum of London site code, by which the records are indexed and archived, is OL-02007. The Ordnance Survey national grid reference are: Henniker's Ditch: 537818 185344, Potter's Ditch: 537694 185309, the Channelsea River: 537684 185232.

1.1.2 OL-02707: The Pudding Mill River

Located in PDZ3, the course of the river was recorded from its confluence with the River Lea in the north to its culverted end 340m to the south-south-east. Banks and structures were recorded where possible. No BH number was assigned. The Museum of London site code, by which the records are indexed and archived, is OL-02707. The Ordnance Survey national grid reference was: 53758 18392

1.1.3 OL-03007: Carpenter's Lock

Located on the River Lea between PDZ 4 and PDZ2 (Figure 9). OL-03007 was known for reference in the project as BH73. The Museum of London site code, by which the records are indexed and archived, is OL-03007. The Ordnance Survey national grid reference was: 537654 184411.

1.1.4 OL-03507: The City Mill River Footbridge

Just south of Carpenter's Lock, linking PDZ3 and PDZ2 (Figure 10). OL-03507 was known for reference in the project as BH75. The Museum of London site code, by which the records are indexed and archived, is OL-03507. The Ordnance Survey national grid reference was: 537654 184348.

1.1.5 OL-05007 Old Ford Locks

Located on the Lea Navigation in PDZ4, these were just north of the waterway's confluence with the River Lea (Figure 5). OL-05007 was known for reference in the project as BH62. The Museum of London site code, by which the records are indexed and archived, is OL-05007. The Ordnance Survey national grid reference was: 537352 183468.

1.1.6 OL-05407: Pudding Mill Lock

Located across the channel of the River Lea, north of Old Ford Locks, linking PDZ4 and PDZ3 (Figure 6). OL-05407 was known for reference in the project as BH80. The Museum of London site code, by which the records are indexed and archived, is OL-05407. The Ordnance Survey national grid reference was: 537480 184088.

1.1.7 OL-07207: Stone and Brick Riverbank Walls

Located on the west bank of the River Lea in PDZ3 (Figure 8). OL-07207 was known for reference in the project as BH70. The Museum of London site code, by which the records are indexed and archived, is OL-07207. The Ordnance Survey national grid reference was: 537327 183896.

1.1.8 OL-07307: Old Ford Lock Houses

Associated with Old Ford Locks in PDZ4, OL-07307 were known for reference in the project as BH71 (Figure 4). The Museum of London site code, by which the records are indexed and archived, is OL-07307. The Ordnance Survey national grid reference was: 537386 184010.

1.1.9 OL-07407: Marshgate Lane Lock

East of Marshgate Lane in PDZ8 (Figure 7). OL-07407 was known for reference in the project as BH 89. The Museum of London site code, by which the records are indexed and archived, is OL-07407. The Ordnance Survey national grid reference was: 538181 183468.

Under the Copyright, Designs and Patents Act 1988 MoLAS-PCA retains the copyright to this document.

Note: within the limitations imposed by dealing with historical material and maps, the information in this document is, to the best knowledge of the author and MoLAS-PCA, correct at the time of writing. Further archaeological investigation, or more information about the nature of the present building may require changes to all or parts of the document.

1.2 Planning and legislative framework

The legislative and planning framework in which the archaeological exercise took place was summarised in the *Archaeological and Built Heritage impact assessments*, previously prepared by MoLAS-PCA, which cover the whole area of the sites (MoLAS-PCA 2007a, 2007b, 2007c, 2007d, 2007e, 2007f, 2007g, 2007h & 2007i) and the *Written Schemes of Investigation* (MoLAS-PCA 2007j, 2007k, 2007l, 2007m, 2007n, 2007o, 2007p & 2007q), which formed the project designs for the survey.

These documents should be referred to for information on the natural geology, archaeological and historical background of the sites, and the initial assessment of their archaeological potential.

None of the structures are Scheduled Monuments, nor are they listed as buildings of special architectural or historic interest. The areas covered fall within LPA Areas of Archaeological Interest.

1.3 Planning background

1.3.1 Planning Delivery Zones 1, 2, 3, 4, 5, 6 7 and 8

In accordance with local and national policies, archaeological evaluation and built heritage survey of the areas of PDZ1, 2, 3, 4, 5, 6 7 and 8 to be impacted upon in advance of its redevelopment was required as part of the planning process. Evaluation is intended to define the archaeological potential and significance of any deposits present on the site, so

that the local authority can formulate responses appropriate to any identified archaeological resource.

The recording of the subject site(s) in PDZ 1, 2, 3, 4, 5, 6 7 and 8 will be undertaken in support of a condition required by English Heritage and attached to the consent granted by the Olympic Delivery Authority Planning Decisions Team with respect to Olympic, Paralympic and Legacy Transformation Planning Application Reference 07/90010/OUMODA and Site Preparation Planning Application Reference 07/90011/FUMODA. Condition SP.0.39 of planning permission 07/90011/FUMODA states:

Demolition of any historic building specified for recording in the submitted Built Heritage Written Schemes of Investigation shall not take place until the recording set out in the relevant Written Scheme of Investigation has been undertaken and written confirmation received from English Heritage that the recording is satisfactory and that the building can be demolished. A report detailing the recording shall be submitted to the Local Planning Authority within six months of the written confirmation received from English Heritage.

Reason: To ensure that buildings with an identified historic interest are recorded.

1.3.2 Planning Delivery Zone 15

In accordance with local and national policies, archaeological evaluation and built heritage survey of the areas of PDZ15 to be impacted upon in advance of its redevelopment was required as part of the planning process. Evaluation is intended to define the archaeological potential and significance of any structures present on the site, so that the local authority can formulate responses appropriate to any identified archaeological resource.

The recording of the subject site in PDZ15 will be undertaken in support of a condition required by English Heritage and attached to the consent granted by the Olympic Delivery Authority Planning Decisions Team with respect to Olympic, Paralympic and Legacy Transformation Planning Application Reference 07/90010/OUMODA. Condition OD.15.2 of planning permission 07/90010/OUMODA states:

Demolition of any historic building specified for recording in the submitted Built Heritage Written Schemes of Investigation shall not take place until the recording set out in the relevant Written Scheme of Investigation has been undertaken and written confirmation received from English Heritage that the recording is satisfactory and that the building can be demolished. A report detailing the recording shall be submitted to the Local Planning Authority within six months of the written confirmation received from English Heritage.

Reason: To ensure that archaeological remains are properly investigated and recorded

1.4 Origin and scope of this report

The archaeological work of analysis and recording, and the production of this report, were commissioned from the Museum of London Archaeology Service and Pre-Construct Archaeology (MoLAS-PCA) by the Olympic Delivery Authority. The work was carried out in accordance with the *Written Schemes of Investigation* (MoLAS-PCA 2007j, 2007k, 2007l, 2007m, 2007n, 2007o, 2007p & 2007q).

Recording and reporting accord with the guidance provided in *Recording Historic Buildings: a guide to good reporting practice* (English Heritage 2006); that is: 'Level 2' for Old Ford Lock Houses, 'Level 3' for the City Mill River Footbridge and 'Photographic Survey' for Henniker's and Potter's Ditches, Carpenter's Lock, Pudding Mill Lock,

Marshgate Lane Lock, Old Ford Locks and the Stone and Brick Riverbank Walls. Due to access issues at Old Ford Lock Houses, only external recording was possible.

The Waterways were recorded using a combination of photographic survey, detailed written descriptions and manual drawings, as also outlined in the specifications set out in *Understanding Historic Buildings: A guide to good recording practice* (English Heritage, 2006).

The report has been prepared within the terms of the relevant standards specified by the Institute of Field Archaeologists (IFA 2001).

This report presents the results of an analytical survey carried out on the site in 2007, combined with the available results of documentary research.

1.5 Research aims and method of work

The research aims of this archaeological work were defined in the *Written Schemes of Investigation* (MoLAS-PCA 2007j, 2007k, 2007l, 2007m, 2007n, 2007o, 2007p & 2007q) in conformity with applicable planning policies and English Heritage guidelines (Archaeological Guidance Paper No. 3, revised June 1998).

The overall aim of the programme of work was to secure ‘preservation by record’ of those aspects of the waterways and standing buildings that were of architectural, archaeological and historical interest. The scope of the work as defined in the *Written Schemes of Investigation* was as follows:

The waterways, Henniker’s and Potter’s Ditches, Old Ford Locks, Pudding Mill Lock, Marshgate Lane Lock, the Stone and Brick Riverbank Wall and Carpenter’s Lock were recorded using photographic survey. Old Ford Lock Houses were recorded to ‘Level 2’ and the City Mill River Footbridge was recorded to ‘Level 3’.

Photographic survey:

‘The structure will be viewed, described and photographed. A photographic survey differs from other surveys in that it provides a very full visual record, accompanied by a brief written account, but without an analytical or drawn survey at a comparable level of detail. Drawings in the form of sketches may be undertaken if required. The structures’ type/purpose, the materials used in their construction and their possible dates of construction will be summarised (MoLAS-PCA 2007, 3.3).

Level 2:

‘The exterior and interior of the structure will be viewed, described and photographed. Sketch plans of the interior and elevations of the exterior will be undertaken. A brief written description will be undertaken, and a report presenting conclusions regarding the development and use of the structure will be produced’ (MoLAS-PCA 2007, 3.3).

Level 3:

‘The exterior and interior of the structure will be viewed, described and photographed. Measured plans of the remains will be undertaken. A systematic written description will be undertaken, and a report presenting conclusions regarding the development, use, historical context and significance of the structures will be produced (MoLAS-PCA 2007, 3.3).’

A landscape survey was also undertaken on the Pudding Mill River.

The investigation satisfied the research aims, and it was determined that it would not be necessary to investigate the structures further during alteration or demolition.

1.6 Organisation of this report and conventions used

Section 2 outlines the topographical and early historical background of the area, on a PDZ by PDZ basis.

Sections 3 to 11 cover the development and function of the waterways:

- Section 3 their early history;
- Section 4 the River Lea and the Lea Navigation;
- Section 5 the Channelsea and Waterworks Rivers;
- Section 6 the City Mill, Pudding Mill and Bow Back Rivers;
- Section 7 the Back Rivers during the 1920s and early 1930s;
- Section 8 the 1930s;
- Section 9 the impact of the railways on the canals;
- Section 10 the impact of the Second World War;
- Section 11 the back rivers from the post-war period onwards

Section 12 outlines the development and function of the recorded structures, while Section 13 incorporates the results of the recording exercise undertaken on site.

Section 14 is a contextualising discussion, followed by conclusions (Section 15) and discussion of potential (Section 16).

A series of appendices follow.

- Appendix 1 contains the NMR OASIS archaeological report forms
- Appendix 2 a glossary
- Appendix 3 the list of photographs
- Appendix 4 the list of working drawings

To aid navigation around the documents, all illustrations are included sequentially in separate appendices: Appendix 5 is the figures; Appendix 6 is the plates

All dimensions are given in metres or millimetres and in feet and inches where appropriate. Heights are given where appropriate in metres above Ordnance Datum (mean sea level), abbreviated 'm OD'.

Table 1 Abbreviations used in this report

2 Topographical and early historical background

A detailed description of the geology, archaeology and history of the site was outlined in the earlier Archaeological and Built Heritage assessments (MoLAS-PCA 2007a, 2007b, 2007c, 2007d, 2007e, 2007f, 2007g, 2007h & 2007i). A brief, contextualising, summary is provided below.

2.1 Geology and natural topography

The waterways are located within and around PDZs 1, 2, 3, 4, 5, 6, 7, 8 & 15 on the Olympic site.

Within this section the topography of each zone is summarised (below).

2.1.1 Planning Delivery Zone One

PDZ1 is located within the wide floodplain of the Lea Valley, c 3.5km to the north of the confluence with the River Thames. The Lea flows through this stretch of the valley via a series of canalised and culverted channels, commonly referred to as the Stratford Back Rivers. The local drift geology consists of a complex sequence of interstratified Holocene alluvial peats and clays sitting on a basal surface of terrace gravels overlying London Clay (British Geological Survey 1996, sheet 257). The Holocene alluvial peats and clays constitute an archaeological horizon, and accordingly are identified as having archaeological potential

Modern ground level at the south of the site along Carpenter's Road is at 3.7m OD, and rises to 5.20m OD at its north-east corner (White Young Green, project EO3778, drawing SK03.c). A recent ground conditions assessment indicates that the Holocene alluvial deposits have surface levels of between 2.12m and 1.70m OD, with base levels of -1.41m OD to -2.13m OD (White Young Green 2004, Table 3.1). A layer of peat measuring 0.5m thick was also encountered (White Young Green 2004, 30). In contrast the surface of Pleistocene gravel lies between c +0.5m OD to +2m OD, probably rising from +0.5m OD at the east of the site to +2.0m OD at the east of the site, away from the Waterworks River towards the northern and eastern boundaries of the zone.

2.1.2 Planning Delivery Zone Two

PDZ2 is located roughly in the middle of the valley floor, c 3.5km to the north of the Lea's confluence with the River Thames. The site is bounded on three sides by river channels. The River Lea, which is tidal for some distance upstream, forms the zone's northern boundary, with its western and eastern sides following the canalised City Mill and Waterworks Rivers respectively. Modern ground level across the site lies at around 6m OD. The edge of the valley floor lies c. 500m to the west and c. 900m to the east of the site, where the ground rises up the valley sides onto the river terrace.

The British Geological Survey Sheet 256, North London shows that the site lies on alluvium, which represents a range of different wetland and dry land environments existing on the valley floor ('floodplain') of the Lea from the Mesolithic period onwards. Although little archaeological work has previously been undertaken in the local area, excavation in the valley of the Thames and its tributaries suggests that archaeological remains of the prehistoric and earlier historic period are likely to lie within the alluvium.

2.1.3 Planning Delivery Zone Three

PDZ3 is located on the western side of the floodplain (valley bottom) of the Lea Valley, between the River Lea and the City Mill River, which form the western and eastern boundaries of the site respectively.

Modern ground level across the site lies at around 4m to 6m OD. The edge of the valley floor lies *c* 200m to the west and *c* 1.1km to the east of the site, where the ground rises up the valley sides onto the river terrace.

The British Geological Survey (Sheet 256) shows that PDZ3 lies on alluvium, which represents a range of different wetland and dry land environments existing on the valley floor ('floodplain') of the Lea from the Mesolithic period onwards. The alluvium overlies gravels and associated deposits of Pleistocene (Palaeolithic) date. The higher ground of the gravel terrace, which forms the western side of the valley, lies immediately west of the site, on the opposite side of the River Lea.

2.1.4 Planning Delivery Zone Four

PDZ4 is located on the western side of the floodplain (valley bottom) of the Lea Valley, between the Hackney Cut and the River Lea, which form the western and eastern boundaries of the site respectively.

The landscape of the site in the past will have been very different to its characteristics today. In particular, the dumping of thick 'made ground' deposits in many areas has obscured its ancient topography. MoLAS-PCA produced a detailed study for the Olympics project entitled '*Ground disturbance and ground raising and the implications for archaeological strategies*' (July 2005). The study shows that PDZ4 contains an infilled an East London Waterworks Company reservoir and associated channels occupying approximately one-half of the site. The MoLAS-PCA site visit noted that the ground level of the Bow Industrial Park is *c*. 1m higher than the level of the canal path on the western side of the site, indicating at least *c*. 1m of modern land-raising material.

The British Geological Survey (Sheet 256) shows that the site lies on alluvium, which represents a range of different wetland and dry land environments existing on the valley floor ('floodplain') of the Lea from the Mesolithic period onwards. The alluvium overlies gravels and associated deposits of Palaeolithic date. The higher ground of the river terraces (the Kempton Park and Taplow Gravels) lies *c* 200m west of the site, on the opposite site of the Hackney Cut.

2.1.5 Planning Delivery Zone Five

PDZ5 is located just west of the centre of the Lea floodplain, close to the confluence of the Lea Valley with the valley of the Hackney Brook. Its western and eastern boundaries follow the Lea Navigation and River Lea respectively, but these modern rivers are much modified by man. In particular, the Lea Navigation is entirely man-made and its construction took place at some time after the passing of the River Lea Act of 1766, which approved major alterations to eliminate loops in the river. As a result, the Lea flows to the east of the Hackney Marshes whereas the new cut of the Lea Navigation runs along the west of the valley from Lea Bridge to Old Ford Locks. Earlier, smaller scale, schemes are likely to have straightened the course of the Lea itself and its ancient abandoned courses lie buried on the valley floor.

The British Geological Survey (Sheet 256) shows that the site lies on alluvium, which represents a range of different wetland and dry land environments existing on the valley floor ('floodplain') of the Lea from the Mesolithic period onwards. Gravels, deposited

following the scouring-out of the valley floor during the Palaeolithic period (the Pleistocene) underlie the alluvium. The base of the gravels, or surface of Tertiary bedrock (which in this area is variably London Clay and Woolwich and Reading Beds) acts as the bottom line for deposits of archaeological interest.

Modern ground level in the north of the site is at around 6–7m OD. Towards the middle of the site near the Hackney Dog Stadium, the ground level is at around 10m OD and to the south of the site along Carpenter's Road, the ground level is at *c* 6m OD. In the west of the site in the Arena Fields area the ground surface is around 10–12m OD.

2.1.6 *Planning Delivery Zone Six*

PDZ6 is located on the eastern side of the floodplain (valley floor) of the River Lea, to the east of the Waterworks River. The modern topography and drainage of the area around the ditch has been much modified by human agency and bears little resemblance to the landscape of the site in historic and prehistoric times. The extent to which Henniker's Ditch and the nearby Channelsea River represent historic watercourses or canalised forms of older watercourses are not yet known. Both rivers are now controlled by sluices, and lie at the base of deep artificial canyons due to extensive ground raising in the area of the Eastway Cycle Circuit, which has masked the natural land surface beneath several metres of 'made ground'.

The site overlies alluvium, which represents a range of different wetland and dryland environments existing within the floodplain of the Lea from the Mesolithic period onwards. These deposits overlie the Lea Valley Gravels, the most recent of a series of Pleistocene river terrace deposits. The underlying London Clay forms a bottom line for deposits of archaeological interest, as its formation predates human evolution.

Modern ground level immediately adjacent to the site lies at *c* 6m–9m OD.

2.1.7 *Planning Delivery Zone Seven*

PDZ7 is located on the eastern edge of the River Lea floodplain, just south of the confluence of the Lea Valley with the valley of the Leyton River, which formerly flowed north-east to south-west across the site from the valley side. No trace of the Leyton River remains above ground today, however its valley is reflected in the present topography, and a modern drainage channel beyond the northwest boundary of the site may reflect its course. This channel flows into the River Lea, which crosses the south-west corner of the site.

The modern topography and drainage of the site has undergone notable modification by man and bears little resemblance today to the landscape of the site in historic and prehistoric times. Modern ground raising has masked the natural land surface by several metres of made ground. Very little remains in the modern landscape of the natural course of the Lea, which now flows through a series of mostly man-made, canalised and culverted channels.

The British Geological Survey Sheet 256, North London, indicates that PDZ7 lies on alluvium, with the Taplow Gravels outcropping a short distance beyond its eastern boundary, where the ground rises up onto the river terrace. The alluvium represents a range of differing wetland and dryland environments existing on the valley floor/floodplain of the Lea from the Mesolithic period onwards.

The alluvium is underlain by the Lea Valley Gravels, deposited following the scouring-out of the valley floor during the Palaeolithic period (the Pleistocene). The gravels are the most recent in a series of Pleistocene river terrace deposits, which today form an irregular flight

of steps in the valley side. The Kempton Park Gravels and older Taplow Gravels form the lowest of these river terraces at the edge of the valley.

Tertiary bedrock, which in this area is variably London Clay and Woolwich and Reading Beds, underlies the gravels. The bedrock pre-dates the period of human evolution and thus its surface acts as the bottom line for deposits of archaeological interest.

Modern ground level in the former cricket ground area of Eton Manor Sports Ground lies at 6.0m OD, and to the south-east of the former sports ground at 5.9m OD, sloping very slightly to 5.1m OD near the junction of Temple Mills Road and Quatermile Lane to the south-west.

2.1.8 Planning Delivery Zone Eight

PDZ8 is located roughly in the middle of the valley floor of the River Lea, c. 3km to the north of its confluence with the River Thames. The zone covers the south-eastern part of a grid-like network of river channels known as the Back Rivers, which are bounded to the south-west by the River Lea, and to the north-east by the canalised Waterworks River. The Bow Back River also flows through the site, the south bank of which forms the southern boundary. The City Mill River crosses the central area of the zone. The modern topography and natural drainage of the zone has been extensively modified over time. It currently bears little resemblance to the natural landscape present in both historic and prehistoric times. Modern ground rising has masked the natural land surface by several metres of 'made ground'. Similarly, very little remains in the modern landscape of the natural course of the Lea, which today flows through a series of mostly man-made canalised and culverted channels, such as those bounding and crossing the site itself.

In addition, now infilled or buried watercourses flowed across the site. The Pudding Mill River, now culverted, formerly flowed across the site alongside Pudding Mill Lane, and other historic channels, now backfilled, also formerly crossed parts of the site

Modern ground level across the site lies between 4m and 6m OD. The edge of the valley floor, where the ground rises up the valley side onto the river terrace, roughly follows the south-west boundary of the site. The eastern valley side lies c 1km to the east of the eastern boundary of the site and is less pronounced than the western side.

2.1.9 Planning Delivery Zone Fifteen

PDZ15 lies at the eastern edge of the River Lea floodplain and forms the south-eastern part of Hackney Marshes, which are open recreation land today.

The modern topography and drainage of PDZ15 has undergone notable modification by man and bears little resemblance to the landscape of the site in historic and prehistoric times. The natural land surface has been masked by several meters of modern made ground. Consequently, very little remains in the modern landscape of the natural course of the Lea, which historic maps show has been straightened in recent time, if not previously. Its tributaries have also been manipulated and diverted, for power, transport, drainage and water supply, with natural and man-made courses infilled and obscured.

Modern ground level at the dressing rooms in the south-west corner of PDZ15 is at 7.5m OD and at 6.92m OD at the northwest end of the footbridge in its north-west corner. A short distance beyond the eastern boundary of the zone, the valley side rises up through Leyton to Walthamstow and Leytonstone, and 500m east of the zone the modern ground surface lies at 13m OD.

Previous geoarchaeological modelling, based on the geotechnical site investigation work currently in progress and on historic borehole data, suggests that the zone is located at the

eastern edge of the Lea valley floor, in a location that is likely to have been influenced by streams draining down the valley side and onto the floodplain of the Lea, as well as the channels of the Lea itself, from prehistoric until recent times. The top of *in situ* alluvium probably lies at *c* 3–4m OD.

3 Development and function of the waterways: early history

3.1 Introduction

The waterways of London have played a vital role in its development, carving out valleys on their way down to the Thames, creating a landscape on which the city is built and thrives (Barton, 2005: 69). Roads often parallel the courses of rivers: a good example is the East Cross Route and the Blackwall Tunnel Northern Approach, which run alongside parts of the River Lea and the Lea Navigation. There is also a profusion of street names and establishments which derive their names from the now largely defunct rivers, channels and canals nearby. Hackney, the very name of the borough, is a name which refers to an island, or 'ey', in the Hackney brook, in combination with the name of the original Danish owner, either Haca or Harcon. Sanford Lane and Sanford Terrace recall the ford at the Cambridge road. Many other streets in Hackney have watery names, some of which refer to the Hackney Brook. The river even appears in the arms of the borough, as 'the base Barry wavy of six Argent and Azure' (Barton, 2005: 70).

The River Lea and many of the waterways which now spring from it were established and in use from at least the medieval period. They have been an essential public utility and a vital resource for both trade and industry from the medieval period to the present day.

3.2 Lost rivers

Many of the rivers within the study area have shifted their courses through time (with the exception of the Lea Navigation – an 18th-century canal). The courses they formerly followed have become infilled, yet they survive close to these former courses. Some rivers, however, have been entirely obscured and leave no remnants in the current landscape. These are lost rivers.

3.2.1 *The 'Old River'*

A river, since lost, once flowed between a point on the Lea a short distance to the west of the mouth of Pudding Mill River to a point on the Lea above Bow Bridge. The course of the stream marked the eastern limit of the parish of St Mary Stratford Bow, and both Gascoigne's and Cardwell's parish maps of 1703 and 1768 respectively label it 'The Old River' (Figures 11 & 12). Chapman and Andre depicted it upon their map of London and Essex 1777 (Figure 13).

During the 19th century the river slowly disappeared as London's infrastructure expanded eastwards; by 1869 the construction of two settling reservoirs (1821-1828), the London to Romford railway (1839) and the Northern Outfall Sewer embankment (1860) had reduced it to a pair of sinuous truncated ditches at its northern and southernmost extents, its former course in-between marked by the now 'undefined' parish boundary (Figure 14). By 1894-6 only the northernmost stretch remained, the outfall to the Lea at Bow Bridge having been culverted or filled after the Bow Back River between Bromley Lock and Marshgate Lane Lock was straightened in c1891 (Figure 15).

The 'Old River' consisted of two south-east flowing channels, connected by a diagonal south-westerly cut, a layout reminiscent of the City Mill River to the east, and indicative of some degree of intentional alteration. The linear channels immediately above the mills on

the Back Rivers helped millers to maintain both an unimpeded flow and a sufficient fall (or head) of water necessary to power their wheels as the tide ebbed (Jones, 2000: 7; Watts, 2002: 89-91), and it is possible that the Old River had once been modified for the same purpose. The possibility that the 'Old River' may have been the site of the 'lost' corn mill belonging to the St Thomas of Acre Hospital, which like the fulling mill on the adjacent Pudding Mill River was also known as St Thomas' Mill in documents dating to the 13th to the 15th centuries, should not be discounted.

3.2.2 *The Hackney Brook*

The Hackney Brook was a tributary of the Lea, a stream of considerable size which lay within the Bow Back Rivers area and is now wholly lost.

It arose by two heads near the Holloway Road and flowed east, passing close to the former Highbury Stadium and forming the northern boundary of the Abney Park cemetery. After crossing what was the road to Cambridge by a sandy ford, it turned southwards and, skirting Hackney Downs, curved round to the east again to cross Mare Street (which significantly, was '*Merestret*' in 1443) as a watersplash. The lower part of the main stream continued through Hackney Wick and joined the Lea a little farther south and is very close to the Lea Navigation.

The Report on the Public Bridges of Middlesex in 1825 described the brook's superficial width at flood as 70ft at Newington and Homerton Bridges, and 100ft at the Hackney Wick Bridge (Barton, 2005: 58-59) (Figure 16).

3.2.3 *The Leyton River*

The Leyton River, which enters the Lea Valley floodplain to the north of PDZ6 may have crossed the area (MoLAS-PCA 2007r, 9, 15-17).

It is not known, however, whether this tributary passed across the area of the Olympic Park or whether it flowed directly west, skirting the higher ground in the eastern part of the Lea valley floor.

Ancestors of both the modern Henniker's Ditch and Channelsea River, even though both are man-made in their present form, may derive from the Leyton River.

3.2.4 *An unnamed river*

Immediately north of the junction of the Pudding Mill River and The Lea, another minor watercourse flowed northwards from the Lea, across the area of PDZ5 to rejoin The Lea just north of Temple Mills.

This watercourse was extant in 1869 (and must have been open at earlier dates) (MoLAS-PCA 2006, fig 2a), was also present in 1896 (MoLAS-PCA 2006, fig 3a), but had been infilled by 1916 (MoLAS-PCA 2006, fig 4a)

3.3 Early industry on the back rivers to c1739

3.3.1 *Wiggen / Abbey Mill on the Channelsea River*

Wiggen Mill was the first mill recorded by name in the area, purchased by Queen Maud (d.1118) at the beginning of the 12th century and given to Barking Abbey as part of an endowment for the upkeep of Channelsea and Bow Bridges (VCH Essex, 1973: 58, 89, 90).

The bridges and their endowments were taken over by Stratford Abbey at some point after 1135, and remained in monastic hands until the Dissolution.

It is likely that the Abbey had a wharf at the mill in the 15th century (VCH Essex, 1973: 59). The two waterwheels ground corn in the 16th century, probably producing flour until the 1570s to supply local bakers who were licensed to sell bread in London (Strong, 2000: 11). Following the Dissolution the mill was granted to the Meautis family, in whose hands it remained until 1633, after which went through several changes of ownership until it ended up in the possession of Christ's Hospital by 1682, which retained the freehold until 1914 (VCH Essex, 1973: 68-70, 89) (Figure 13).

3.3.2 Temple Mills, Saynes Mill on the Waterworks River

Before major alterations were made in the 19th and 20th centuries, the Waterworks River branched from the east bank of the Lea above Temple Mills, a stretch known as the Temple Mills Stream as late as 1834 (ACC/2423/P/1703 (ii)).

Below Temple Mills the river headed south roughly parallel to the Lea, before briefly rejoining it at an intersection known as the Bully Fence. The river then ran south-east towards the London – Stratford road, pursuing a straight course above Saynes Mill. Below the mill, but still north of the road it split into two branches, which passed under it at St Michael's and St Thomas' (renamed Pegshole after 1814) Bridges, below which the branches rejoined to form the Three Mills Wall River and headed south via Three Mills to Bow Creek. Below Temple Mills the river was known as the Shire stream until c1745, after which it became known as the Waterworks River.

In the vicinity of Temple Mills a number of medieval channels drained into the Waterworks River from the east. The most significant of these marked the eastern boundary of Leyton Marsh between Walthamstow and Temple Mills Lane, and became known as the Dagenham Brook in the late 19th century (ACC/2423/P/0601; VCH Essex, 1973: 201). This ditch was the common sewer of the Havering and Dagenham Commissioners of Sewers, the authority responsible for land drainage in the area until the 1930s (VCH Essex, 1966: 75). The final stretch of this sewer headed east alongside Temple Mills Lane until it discharged into the Waterworks just above Temple Mills. This channel was frequently blocked during the 16th and 17th centuries, causing floodwaters to overflow into the surrounding marshes. Many of those who complained to the Commissioners about the flooding identified the occupants of Temple Mills as the cause of the problem, as they were known to keep their floodgates closed for extended periods during spring tides in order to ensure the highest possible pen of water (*ibid*).

The Temple Mills themselves comprised a pair of watermills which over time had ground corn, milled gunpowder, ground oil from rapeseed, milled timber and were being used as a brass kettle factory and possibly a yarn twining works in 1739 (VCH Essex, 1973: 198, 199).

The earliest recorded mention of Saynes Mill dates from the early 13th century, after which both it and Spilemans Mill on the City Mill River became part of the endowment of London Bridge (VCH Essex, 1973: 91). The mills remained in the hands of the Bridge House Committee (later Estate) of the City Corporation well into the 19th century, and were let to tenants on long leases. In 1739 the tenant was a John Cox of West Ham, who held the mills and about 30 acres of land from the Bridge House Estate (COL/PL/01/049/B: 352; 365; VCH Essex, 1973: *ibid*). Saynes Mill appears to have been used to grind corn throughout most of its working life and from c1720 a windmill that stood within the grounds was used by the millers as an auxiliary source of power when the waterwheels were prevented from working when the Lea was in flood (Fairclough, 2003: 5; VCH Essex, 1973: 91).

Above Temple Mills a calico ground stood on the Leyton side of the Waterworks River in the mid-18th century (VCH Middlesex, 1995: 94), an isolated outpost of industry in the midst of an area that otherwise remained primarily marsh grazing land into the 19th century. Historical mapping also confirms that the banks of the Waterworks above Saynes Mill were also largely featureless marsh and pasture until the 19th century.

3.3.3 *Spilemans Mill on the City Mill River*

The City Mill River branched from the east bank of the Lea below the Bully Fence and flowed south-east towards the London – Stratford road, following a straight course until it curved south-westwards, below which it resumed a straight course towards Spilemans Mill. Above the mill it bifurcated, forming the Bow Back River, which headed west to join the Lea above Bow Bridge, and the Three Mills Back River, which joined the Pudding Mill River and flowed under the road at St Thomas’ (renamed Pegshole after 1814) Bridge. South of the road this river was known as the Three Mills Back River, which joined the Three Mills Wall River above Three Mills itself. These rivers provided the pound for the Three Mills, which depended upon the accumulated tidewaters to drive up to seven waterwheels (Strong, 2000: 16).

The Bridge House Estate leased Spilemans Mill to fullers during the 13th and 14th centuries, although by 1615 one of the two mills on the site was producing gunpowder (*ibid*). It appears that one was rebuilt as a corn mill in the middle of the 17th century, after which both mills experienced alternating periods of activity and abandonment until the 1730s (*ibid*). The site consisted of the two watermills and ancillary structures, with five acres of meadow and two windmills (ACC/1037/99), and lessees regularly sublet parcels of land and machinery to other local business tenants (e.g. ACC/1037/103/1).

Above Spilemans Mill much of the land on either side of the river was still pasture as late as the end of the 19th century, and it is unlikely the banks were revetted. A series of sections of the Back Rivers surveyed in advance of a Lea Conservancy Board dredging programme revealed that both banks at the top of the City Mill River remained entirely ‘natural’ as late as 1908 (ACC/2423/P/1747/2).

3.3.4 *St Thomas’ (Fotes) Mill on the Pudding Mill River*

Before extensive modification during the 1920s, the Pudding Mill River branched from the south-east bank of the Lea west of and parallel to the City Mill River, and pursued a south-easterly course towards St. Thomas’ Mill. Below the mill it joined the sinuous Bow Back River above the London – Stratford road.

Fotes Mill was first mentioned in 1200. By the middle of the 13th century both Fotes and another mill, since lost, were owned by the hospital of St Thomas Acre (VCH Essex, 1973: 90). Initially a fulling mill, it was grinding corn in the early 14th century, which it continued to do for much of the next three hundred years, aside from a brief interlude as a gunpowder mill at the end of the 16th century (VCH Essex, 1973: 91).

After the Dissolution the freehold of the mill passed through the hands of several owners who let it to tenants on long leases. In 1734 Peter Lefevre acquired the Lease of St Thomas’ Mill, and established the Stratford Distillery at the site shortly afterwards (Fairclough, 2003: 8-9; Strong, 2000: 11-15).

4 Development and function of the waterways: the River Lea and the Lea Navigation

4.1 The River Lea and the old Lea Navigation

It is possible that the Lea was navigable during the early medieval period, as the Anglo-Saxon Chronicle records that there was a Danish naval incursion as far north as Hertford in AD 895 (Garmonsway, 1972: 89). By the late 16th century a lucrative land and river-borne trade in cereal and other agricultural commodities had developed between Hertfordshire and London, whereby wheat and malt were transported down the Lea from Ware and Hoddesdon and points in between to the capital (Bull, 1958: 375).

At the time of the great plague in 1665, barges from Hertford and Ware continued their grain traffic to the city and managed to help save London from starvation. As a token of appreciation, barges registered in these towns were allowed to navigate the Thames without the aid of London lightermen. This is still recognised today by the port of London Authority (Denney, 1977: 40).

Efforts by authorities to strike a balance between the competing interests of landowners, millers and navigators became more frequent from the 14th century onwards. Measures taken by millers to secure water power and by landowners to prevent flooding proved increasingly harmful to navigation as the effects of tidal flooding intensified. Commissions of Sewers regularly ordered the removal of unauthorised river diversions and other obstructions to navigation from the 1350s onwards, and Parliamentary Acts for the improvement of navigation were passed in 1424 and 1571 (Bull, 1958: *ibid*; VCH Essex, 1973: 57).

The 1571 Navigation Act demanded that the Lea be made navigable to boats drawing 8' of water as far north as Ware, although this initiative was not extended to the millstreams in the Stratford area (Bull, 1958; 375-8; VCH Essex, 1973: 57). Accounts suggesting that the Act prompted large-scale re-cutting of the Lea channel between Bow and Ware are now generally discounted (e.g. Bull, 1958) and it appears that in the lower Lea Valley it promised much and delivered little, with responsibility for the enforcement of bye-laws and custom remaining in the hands of the local Commissions of Sewers, as before.

It is, however, possible to identify at least one phase of work almost certainly intended to improve the navigability of the Lea that may be attributed to the period before 1740: a linear north-south stretch of the Lea below Temple Bridge known as the Bowling Alley, which was identified as 'The New Cut' in a petition of 1742 (CLA/047/LR/07/020). The 'New Cut' predated the foundation of the Trustees of the Lea Navigation in 1739 (RAIL 845/1), and may have represented a re-cut of a stretch of river that had previously been improved, perhaps in response to the 1571 Act.

4.2 The creation of the Trustees of the Lea Navigation

The flurry of petitions raised by commercial users of the Lea concerning hindrances to navigation encountered during their passage of the river continued unabated into the mid-18th century and beyond. These obstructions arose as a consequence both of neglect and of the endeavours of mill owners to ensure the highest possible pen of water to drive their waterwheels. The latter objective could be achieved either through the construction of

unauthorised dams, diversions and piles in the back rivers (e.g. CLA/036/02/1814/5/3) or by keeping the tide gates on the Lea Navigation closed against traffic ascending and descending the river in order to extract as much power as possible from the penned waters (e.g. CLA/036/02/1828/4/2). Both caused congestion amongst river traffic, and both encouraged the accumulation of sediments in the main and back channels, such as the “*many hills of Gravell Sand*” that confronted barge and boat owners in the Bowling Alley in 1742 (ACC/2423/P/0602) (Figure 16).

The fact that mill owners also demanded turnpike tolls for the privilege of traversing those stretches of the navigation in their care further compounded the complainants’ sense of grievance (RAIL 845/1: 61). Although petitioners were able to seek redress from the Commissioners’ Courts, it was not until 1739 that a Parliamentary Act eventually established the Trustees of the River Lea, a standing authority dedicated to the “preservation and improvement of the Navigation” (RAIL 845/1).

This body further extended its powers by means of an Act of 1767 that created the Board of Trustees of the River Lea Navigation, which promptly revoked the right of mill owners to levy and collect tolls and set about improving the Navigation by sponsoring the construction of new cuts between Hertford and the Thames (RAIL 845/50: 1).

4.3 The New Navigation (Hackney Cut)

In 1766 the Trustees resolved to make good the neglect of earlier years and instructed surveyors John Smeaton and Thomas Yeoman to plan the most cost-effective route for the Navigation between Hertford and the Thames (RAIL 845/3: 4).

Both long- and short-cut options were considered, and a plan of that year offered a choice between a short canalised stretch between Old Ford and Temple Mills or a much longer cut between Old Ford and Lea Bridge and beyond (BL1240. (18)/ACC/2423/P/0602) (Figure 16).

A version of the long-cut option was chosen, and an invitation to tender for the construction of the stretch between Old Ford and Hackney was issued by the Trustees in December 1767 (RAIL 845/50: 61). The following month, Jeremiah Ilsey, a Hackney brickmaker, was commissioned to dig the new cuts at Hackney and Cheshunt, on condition that he would “make the banks sound and handsome and finish the work to the approbation of their [the Trustees’] Surveyor for threepence a yard” (RAIL 845/50: 62). The Trustees considered that a ‘Chain Pump, Boards and Piles’ would be sufficient materials for the completion of the task, although brickwork was commissioned from another local craftsman for the construction of the new lock at Old Ford (RAIL 845/50: 100).

Within weeks of the Hackney Cut opening in August 1769 it was realised that it was necessary to widen the channel in the vicinity of the Hackney Waterworks, in order to reduce the velocity of the water that was proving a hindrance to river traffic ascending the Navigation (RAIL 845/50: 192). A similar problem arose in the newly completed Limehouse Cut between Bromley and Limehouse Dock, and a large-scale programme of widening was ordered in March 1773.

However, aside from the corrective works carried out in response to the 1850 Improvement Act, maintenance in the Hackney Cut during the late 18th and early 19th centuries remained relatively basic, consisting of an annual round of back drain cleansing every August or September and the periodic removal of any shelves (of sediment) that had accumulated at the tails of the locks (RAIL 845/5).

4.4 Industrial development on the River Lea

By the mid-18th century a considerable variety of industrial activity was taking place on the west bank of the Lea between Bow Bridge and Temple Bridge, including calico printing, dyeing, fellmongering and the manufacture of vitriol (sulphuric acid).

By contrast the east bank remained underdeveloped, with osier beds lining much of the bank between Bow Bridge and Old Ford Locks into the second decade of the 19th century (ACC/2423/P/1713, not reproduced). In places the only evidence of development was a towpath, which had been laid out in 1771/2 by the Trustees on the east bank between Bow Bridge and Old Ford (RAIL 845/50: 246).

The east bank's earliest commercial development was the construction of Stratford, later Meggs, Dock, a stone-lined structure of about 80 yards long and 50 yards wide, which stood at the top of a channel cut into the bank just below Bow Bridge between c1800 and 1812 (St Leonard's Bromley parish map of 1812; also ACC/2423/P/0601, not reproduced). It has been suggested that it was built by the Middlesex and Essex Turnpike Trust and later leased by John Meggs, founder of the ladder makers which traded from premises on Stratford High Street until the 1920s (VCH Essex, 1973: 59, 85), although it is not clear whether this was the same as the John Meggs who signed both the 1825 and 1828 petitions.

Despite progressive infilling from its eastern banks the western half of Meggs Dock and the approach from the Lea dock survived until the end of the 19th century, although it seems to have been completely infilled by 1920 (VCH Essex, 1973: 59). Part of the entrance cut still forms a short stretch of the present east bank of the Lea, a short distance east of Hunts Lane.

4.5 The 1850 Improvement Act

By the late 1840s it was apparent that the system that enabled vessels to negotiate the fall along the gradient between Hertford and the Thames was failing to meet the demands of the increasing volume of river traffic. The inadequacies of the existing system had been exacerbated by the continuing failure of the Board and the Conservancy Courts to regulate the activities of those who controlled the tide gates at bottlenecks such as Bromley Lock, forcing owners to lay up loaded vessels for days in the basins below (CLA/036/02/1828/4/2). Partly in response to the criticism from local businesses, the Trustees sought assent for an Act to improve the condition of the Navigation in 1849. The resulting Improvement Act of 1850 proposed a programme of works from Hertford Town Mill to Limehouse, which included a number of important alterations to the Hackney Cut above Old Ford Lock, to the Lock itself and to the navigable section of the Lea (also known as the Bow River) between the Lock and Bromley.

On the stretch above Old Ford Locks a new profile was created as the channel was widened and deepened below White Post Lane Bridge, and the parallel cut of the Hackney Sewer on the west bank was absorbed into the main channel (ACC/2423/P/1480, not reproduced). A new brick-built double-chambered lock replaced the existing single lock at Old Ford and it was intended to add an overshot weir to the west (ACC/24234/P/0557, not reproduced). The straightening and rebuilding of the stretch immediately below the lock on the west bank is also likely to date from this period. It is not clear whether this was completed as part of the lock rebuilding work, or whether it is the sole survival of the scheme to canalise and therefore shorten the Lea between the Lock and Bow Bridge by 140', which was sanctioned by the Act but never completed (ACC/2423/P/0627, not reproduced).

4.6 The water supply of East London, c1809 – c1872

4.6.1 Public water supply from the Lea

For more than 60 years large areas of land on both banks of the Lea between Bow and Old Ford were set aside for the extraction, storage and distribution of a significant proportion of the public water supply of East London.

During the 18th century the earliest shoots of local industrial growth coupled with a rising population created demand for a regular public water supply in the Stratford area. In response the West Ham Water Company began supplying water drawn from the Waterworks River by their works at Saynes Mill in 1745 (VCH, Essex 1973: 57). The West Ham and the nearby Shadwell Waterworks companies had managed to deliver a rather patchy and inconsistent supply before the new East London Waterworks Company absorbed them in 1807 (Select Committee, 1821: 61).

Forbidden from drawing water from the Thames at Shadwell, the new company was ordered to take its water from the Lea, necessitating the construction of a new intake and reservoirs at Old Ford to supplement and ultimately replace the existing works at Saynes Mill (Select Committee, 1821: *ibid*).

4.6.2 The East London Waterworks Company Old Ford Works and Reservoirs, 1809 – c1870

Construction of the waterworks at Old Ford began in 1807, and the completed facility opened in 1809. Initially the works housed four steam engines of between 20hp and 100hp, which raised water from a pair of oval settling reservoirs and pumped it through four cast iron mains to customers across Limehouse, Shadwell, West Ham, Stratford and parts of Mile End (Select Committee, 1821: 54-58).

Water entered the reservoirs on the incoming tide through intakes situated on the west bank of the Lea, the location of which can be identified both on the 'long cut' plan of c1812 (ACC/2423/P/1713, not reproduced), and the 1869 Ordnance Survey map (Figure 14). Once inside, the water stood for two to three days in order that the heavier sediments held in suspension might settle, after which it was raised by the pumps and circulated via the mains (Report of the Commissioners, 1828: 20). Holding up to two day's supply of water, the reservoirs were open brick-lined structures with 1' thick gravel floors approximately 15'6" deep, the bottom 5'6" of which was lower than the bed of the Lea (Select Committee, 1821: 56).

At some point between 1821 and 1828 the company built two larger settling reservoirs on the opposite bank of the Lea (these are mislabelled 'Compensation Reservoirs' on the 1869 Ordnance Survey; (Figure 14). The four reservoirs at Old Ford covered a total of more than 11 acres and supplied over 36,000 customers (Report of the Commissioners, 1828: 19-20). The new reservoirs were also open, but were lined solely with gravel and were only 10' deep (*ibid*). A 36" aqueduct under the Lea connected the reservoirs on either bank, and could carry water from the intake on the west bank to settle in the reservoirs on the east (Report of the Commissioners, 1828: 20). It is not clear whether either of the east bank reservoirs took water directly from the Lea, though Stanford's 'Map of London and its Suburbs' of 1862 does show what appears to have been an overflow from the southernmost of the new reservoirs into the Pudding Mill River.

By 1828 the East London Waterworks Company was supplying 5,900,000 gallons of water each day drawn from the Lea at Old Ford (Report of the Commissioners, 1828: 21). The abstraction of such large quantities inevitably reduced the flow of water in the Back Rivers,

with potentially harmful consequences for the mills that depended upon them for power. As a result an agreement was reached with the Trustees that the company would build a reservoir north of Old Ford between the Hackney Cut and the Old Lea that would compensate for the loss of water, guaranteeing enough to power the mills and ensuring that the rivers remained navigable at low tide (Report of the Select Committee, 1834: 123). Because it was below the tidal limit of the Lea, the triangular 14-acre Compensation Reservoir was filled every incoming tide via an intake from the river at its southernmost end (Figure 14). The accumulated waters were subsequently discharged on the ebb tide via an outfall on the north east side directly into the Old Lea, thereby maintaining levels in the Lea Navigation, the City Mill and Pudding Mill Rivers (ACC/2423/P/0397, not reproduced). Water from this reservoir did not enter the public supply.

The Compensation Reservoir was also supplied by a sinuous channel that flowed into a sluice in its north-west corner from the Old Lea, at the point where the river met Temple Mills Road, which intercepted surface drainage from the fields and marshes to the north (ACC/2423/P/0963; 1894-6 OS London Sheet 32). This channel underwent a number of diversions in subsequent years and seems to have been largely culverted or infilled by 1916.

The reservoir did not discharge water into either the Channelsea or the Waterworks Rivers, both of which received the ebb tide as it flowed down from the tidal limit at Temple Mill. Despite the expansion of the Old Ford works, the Waterworks River continued to function as a reservoir in its own right, from which a 15'3" breastshot wheel at Saynes Mill raised water up to 90'-100' for an average of 12 hours out of every 24 in 1828 (Select Committee, 1821: 60; Report of the Commissioners, 1828: 19). Although Saynes Mill remained in the possession of the company until 1883, it had ceased being used to draw water before 1834, and was demolished before 1892 (ACC/2423/P/1746; VCH Essex, 1973: 91) (Figure 17).

In 1829 the company obtained powers to open an intake higher up the Lea, and the following year purchased the former Hackney Waterworks Company's works at Lea Bridge Mills (VCH Middlesex, 1995: 108). Construction began in 1830 on an open canal to take water from the new intake to the Old Ford reservoirs, and the pipes connecting it with the settling reservoirs on the east bank were laid under the Lea in c1832/3 (ACC/2423/P/0750; Report of the Select Committee, 1834: 121). The canal is somewhat confusingly identified as the East London Waterworks Company Waste Channel on the 1869 Ordnance Survey map (Figure 14).

The company announced in 1834 that the Old Ford intake was to close, and that year water began to be supplied via the new channel from Lea Bridge (Report of the Select Committee, 1834: 121). The change of supply reversed the sequence by which the reservoirs at Old Ford were filled, as water now descended via the canal in a constant slow stream into the northernmost reservoir on the east bank, thence to the reservoir to the south, and subsequently to the two on the west bank, from which it was raised by the pumps (Report of the Select Committee, 1834: 122). A channel that followed the eastern boundary of the upper reservoir on the east bank and entered the lower one via a sluice in its north-east corner allowed the latter reservoir to be filled independently of its partner. The uninterrupted flow from the Lea Bridge intake meant that water was no longer left in the reservoirs to settle and stagnate for several days, a development that convinced the company that there was no need to filter the water before it entered the public supply.

Increasing public scrutiny of the extent and quality of London's public water supply in the wake of repeated cholera outbreaks led to the 1852 Metropolis Water Supply Act, which instructed the water companies to cover all reservoirs within five miles of St Paul's. In response, the East London Waterworks Company covered the reservoirs on the west bank but left the pair on the east open, an infringement which was to cost it dearly the following decade (ACC/2423/EM/052; Correspondence &c, 1867: 11).

The outbreak of cholera that struck East London in 1866 signalled the end for the works at Old Ford. Despite repeated assertions from the company's representatives that unfiltered water drawn from the Lea was safe for domestic use, complaints from customers about the inconsistency and impurity of the water supplied by the company prompted an enquiry by Captain Tyler of the Board of Trade which found merit in two critical allegations regarding the water supplied from the works (Correspondence &c, 1867: 1).

The first charged that water from the Lea at Old Ford had found its way into one of the covered reservoirs on the west bank. Although it was never confirmed precisely how this had happened, the substance of the allegation was proven, and the company sought powers to close the reservoir in 1867. Under this new Act the company provided a filtering area for the surviving reservoir on the west bank, which was also made watertight and partially infilled to in order to raise its floor higher than that of the adjacent riverbed (Correspondence &c, 1867: 11). These modifications appear to have represented a stop-gap measure taken whilst work was undertaken on establishing new intakes on the Lea at Chingford Mill and on the Thames at Sunbury, and it is likely that the surviving reservoir was closed before the Thames supply came into use in 1871/2 (VCH, Essex 1966: 38). Following the closure of the reservoirs, the site was levelled in order to accommodate the Bow Goods Station yard and sidings. Extensive banks were constructed over the site of the former reservoirs, probably using spoil from the mound that had stood a short distance to the north. The adjacent stretch of the west bank of the Lea where the intakes were formerly located was entirely reconstructed when the goods yard and railway bridge over the Lea were built (Figure 14).

Tyler's second allegation concerned the open reservoirs on the east bank of the Lea. In addition to constituting a clear breach of the 1852 Act, it was charged that "no sufficient care was taken to protect the water against impurity" at the reservoirs before it was passed to the covered reservoirs for onward distribution (Correspondence &c, 1867: *ibid*). The company admitted the charges and closed the connection between the reservoirs on either side of the Lea in September 1866. The reservoirs were filled in shortly afterwards under the provision of the 1867 Act (*ibid*). It appears that the closure of these reservoirs was the cue for the long-delayed straightening of the curve in the Lea that had previously defined the south-west 'corner' of the upper reservoir, and corresponding works were carried out on the opposite bank between 1869 and 1894-6 (Figure 15). The overflow that discharged from the lower reservoir into the Pudding Mill River a short distance above the GER line was also infilled when the reservoirs were decommissioned.

In 1892 the East London Waterworks Company sold off the entire site, and by the following year railway sidings between the Northern Outfall Sewer and the G.E.R. mainline covered the site previously occupied by the reservoirs (Weinreib & Hibbert, 1983: 258).

The closure of the open reservoirs and the opening of new intakes at Sunbury and Chingford removed the original *raison d'être* for the East London Waterworks Channel below Lea Bridge. Thereafter maps no longer showed the channel below a point on the Hackney Cut north of the G.E.R. Victoria Park Branch line and the Clarnico Works on the east bank. Above this, however, it survived as far north as Copper Mills. This suggests that it was retained as a flood relief channel (as the 1869 Ordnance Survey caption suggests, Figure 14), possibly serving as both an overflow from the Lea Bridge filtration works in addition to its role as an open intercepting sewer for surface drainage from the marshes to the south. This would imply that the southernmost section was likely to have been culverted rather than simply infilled, and the presence on the 1894-6 Ordnance Survey (Figure 15) of a bank that followed the channel's former north-south course on both sides of the Old Lea before terminating at the point it reached the L.C.C. Northern Outfall Sewer embankment offers some support for this suggestion.

When the West Ham Corporation finally gained admission to the L.C.C. main drainage system in 1893, it is likely that the culverted channel was again diverted, possibly to the Corporation's new pumping station situated just above the Northern Outfall Sewer embankment on the east bank of the Lea south-east of Old Ford Locks (VCH Essex, 1966: 40).

It appears that the Old Ford Compensation Reservoir functioned so long as the company drew water from the Lea below Chingford Mill. However, the construction of new reservoirs at Walthamstow in 1867 (ACC/2423/P/0543/, not reproduced), the opening of the Thames intake above Sunbury in 1872 and the Chingford intake after 1882 must have rendered the Compensation Reservoir redundant by the beginning of the 1880s at the latest (ACC/2423/P/0540; VCH Essex, 1966: 38, not reproduced).

Neither the precise dates of infilling nor the process by which the reservoir was infilled appear to have been documented. The 1894-6 Ordnance Survey map shows the reservoir site after infilling; its north-eastern area is depicted as marsh and the outline of its former banks remain clearly visible. The outlet on the Lea also survived, although it now served as an outfall for the diverted surface drainage channel from Temple Mills Road that had previously fed into the north-west corner of the reservoir. This short-lived channel across the former reservoir had disappeared by 1908, although it is not clear whether it had simply been infilled or had been culverted and redirected, perhaps to the recently built Old Ford Pumping Station. What appears to have been a breach in the west bank of the Lea, possibly made in order to take advantage of the inclined reservoir floor to assist the draining of the reservoir, is visible on both the 1894-6 and 1914-6 Ordnance Survey maps (Figures 14 and 15). The embankments on either side of the outlet gates survived in plan form on the north-eastern bank of the Lea on the 1914-6 Ordnance Survey, whereas the former intake at the southern 'apex' of the reservoir had been entirely filled in and the adjacent stretch of bank reconstructed by 1894-6.

Preliminary drawn sections of the Lea surveyed in association with the 1908 Lea Conservancy Board programme of works show that no trace remained of the intake on the north bank, whilst a stone-built river wall on the opposite bank indicated the location of the Metropolitan Water Board Old Ford Pumping Station. Further sections reveal that the reservoir itself had been completely infilled by 1908, and show a gentle gradient falling southward across the former reservoir site (subsequently occupied by a timber yard) towards the north bank of the Old Lea (*ibid*).

4.7 Drainage and sewerage in the Lower Lea Valley, c1850 – c1890

The continuing growth of industry and population in East London after 1850 placed increasing demands upon the drainage of the Lower Lea Valley, and it became apparent to both parish vestries and the Commissioners of Sewers that the existing provision, which relied upon the pre-industrial network of open sewers to convey surface drainage into the waterways was incapable of coping with the new pressures being placed upon it.

The sheer volume of new residential development without adequate sewerage provision quickly overcame the existing infrastructure and a number of parochial authorities applied for Local Board status in order to exert a greater degree of local control over the problem. Local Boards were established in West Ham in 1857, and in Leyton in 1873 (VCH Essex, 1973: 40, 205). Parliament passed several Acts compelling local authorities to improve sanitary provision in urban areas including the Sanitary Act of 1866, the Public Health Act of 1872 and the Sanitary Laws Amendment Act of 1874, which together defined the responsibilities and powers of local authorities in respect of sanitation and sewage disposal. Hackney District Board of Works took over local sanitary control in 1856, and was

admitted to the Metropolitan Board of Works main drainage system when it was opened in the early 1860s (VCH Middlesex, 1995: 110-115). The West Ham Local Board began to develop an independent main drainage scheme in 1861, whilst Leyton's vestry began work on its main drainage system in 1866 (VCH Essex, 1973: 39, 200, 209).

On completion, both of the latter schemes proved somewhat unsatisfactory and they continued to discharge sewage at various stages of treatment into the Lea and the Back Rivers during the 1860s and 1870s. The Trustees of the Lea Navigation gave the West Ham Local Board temporary permission to discharge untreated sewage into the Lea at Bow Creek from 1861, whilst much of Leyton's sewage, and some from Walthamstow, found its way to the already blocked Channelsea River (*ibid*). Complaints of pollution by neighbouring districts mounted, and a number of Local Boards resorted to litigation in order to restrain their neighbours from polluting their waterways.

The Lea Conservancy Act of 1868 gave statutory responsibility for the prevention of pollution in the Lea and its tributaries to the newly constituted Lea Conservancy Board (L.C.B.) (HLG/50/52). This body, which replaced the Trustees, launched a long-running campaign aimed at cajoling Local Boards and districts the length of the Lea to improve their sewage disposal arrangements. In response both West Ham and Leyton greatly improved local drainage, sewage treatment and disposal during the early 1880s. Both Boards upgraded their treatment works, and by the early 1890s both were separating surface drainage water from the main sewers by building separate storm water drains on the roads (ACC/2423/PP/027; VCH Essex, 1973: 38-40, 209, 210). These and other improvements helped to alleviate the worst of the pollution in the Back Rivers, though they were at best to prove a temporary solution to a much larger problem.

4.8 The Bow Back River and the River Lea between c1850 and c1890

Little new work was carried out on the Bow Back River during the period. The problems of silting and tidal flooding in the Back Rivers, which were intensified by the rising levels of river-borne pollution, are likely to have affected the 'natural' and man-made inlets that lined the channel, and considerable effort would have been required to keep them in working order.

On the east bank of the Lea development infilled the hitherto underused land between Bow Bridge and the G.E.R. railway bridge. Above this the banks were rebuilt following the closure of the East London Waterworks Company's reservoirs, and the area behind became occupied by sidings. On the west bank an inlet in the triangular garden between the river, Old Ford Road and the G.E.R. bridge was infilled after 1869, and a vertical stone bank, later capped in concrete, erected in its place. The plot was later occupied by a timber yard, and the bank, its timber fenders and mooring rings survive (MoLAS-PCA, 2005: 4.4.1). North of the Bow Goods Yard the original stone-built wharf walls used by the Printing Ink Works and the Iceland Wharf Ammonia Works survived the rebuilding of the west bank after the closure of the covered reservoirs, and the walls depicted on the 1869 Ordnance Survey still survive (*ibid*).

4.9 Flood prevention programmes and protective works on the Lea and the Back Rivers, 1890 – 1935

4.9.1 Lea Conservancy Board flood relief and canalisation to 1829

The sewerage works of the 1860s to the 1890s succeeded in treating and taking foul sewage away from homes and workplaces, but did not address the broader problem of drainage in the Lea Valley. During the early years of the 20th century increasing quantities of treated effluent and storm water drainage discharged by the expanding districts upstream of the tidal limit at Temple Mills accumulated in the Back Rivers, “washed backwards and forwards at every state of the tide” according to the Hackney Borough Engineer in 1921 (HLG/50/49). An ever-growing quantity of silt settled on the beds of the Stratford Back Rivers, creating potential obstructions to navigation, blocking wharves and causing floods along the banks.

In 1891 the L.C.B. published plans for a scheme intended to alleviate the flooding by partially canalising the Back Rivers and parts of the Lea between Old Ford Lock and the Carpenter’s Road Bridge (Figure 14). It was also hoped to make the lower course of the Waterworks, the City Mill, and the Pudding Mill River above St Thomas’ Mill fully navigable. However, the Parliamentary Bill promoting the scheme was withdrawn before it received assent after opposition from river users and certain upstream districts to the levying of tolls to fund and maintain the system.

Although the 1891 programme was never fully realised, certain elements resurfaced over the following years, some under the guise of the 1908 Back River cleaning programme (ACC/2423/P/1747).

Furthermore, a number of important alterations not associated with the scheme were made to the Bow Back River following the development of Cook’s Road, and to the east–west stretch of the Waterworks River during the late 1880s and early 1890s, which were to transform the banks along both waterways.

In the wake of the 1891 programme and the Bow Back River improvements, ambitious plans were submitted to Parliament by the West Ham Corporation for the widening of Stratford High Street on the south bank of the Waterworks (ACC/2423/PP/027/371, not reproduced). The Corporation and the Bridge House Estate also submitted plans, for the laying out of a new road network upon the hitherto neglected area between the City Mill and Waterworks Rivers, which was to be linked to Warton Road by a new road bridge (ACC/2423/PP/027/368, not reproduced).

Although neither of these schemes took off, an increasingly well-documented process of piecemeal repair, infilling and rebuilding of banks elsewhere on the waterways continued throughout the period, prior to the large-scale rebuilding of the 1930s.

4.9.2 The River Lea and the Hackney Cut between 1891 and 1935

Extensive stretches of the banks of the Lea between Bow Bridge and Old Ford Lock were rebuilt or repaired during the early decades of the 20th century. A steel coffered bank on the east bank between the Bow Interchange and Old Ford Lock was constructed of uncapped Larsen 12” x 5” steel piles, tied into the banks by steel tie-bolts (ACC/2423/P/0156 not reproduced; MoLAS-PCA, 2005: 4.5.3). Similar techniques and materials were used in the reconstruction of Liberty Oils Wharf, a short distance above Bow Bridge on the west bank (ACC/2423/P/2568). 15” x 5” x 16’ interlocking Larsen sheet steel piling was used to rebuild approximately 20’ of the company’s river frontage,

anchored by ties embedded in the banks behind. The new wharf wall was capped with a reinforced concrete kerb (Figure 18).

Neither the 1891 nor the 1908 plans to partially canalise the Old Lea between Old Ford Lock and Carpenter's Road Bridge were realised, and works were confined to the infilling of the old Compensation Reservoir intake and outlet, and to the short stretches of remodelled banks in the vicinity of the Back River intersections. However, from the turn of the 20th century, Board engineers had repeatedly advocated the construction of a new lock or pair of flood gates on the Lea above the Pudding Mill intersection, intended to replace the tide gates a short distance to the south-west at Old Ford. The Pudding Mill Lock was eventually constructed between c1922 and c1928, a short stretch of the bank narrowed and the towing path rebuilt (Figure 19).

Before the beginning of the 20th century, the banks of the Hackney Cut had remained largely unaffected by commercial development south of the noxious industries on White Post Lane (VCH Middlesex, 1995: 95). Following the opening of Clarke, Nicholls and Coombs' Clarnico Works in c1910, the underused east bank became open to development. Much of the present east bank is constructed of uncapped steel piles (MoLAS-PCA, 2006, 4.5.4), and may date to the reconstruction of the towing path in 1929. The contract for this scheme specified that contractors use interlocking British Steel Piling Company 15" x 5" piles, or Universal Joist Steel Sheet Piling and 12" x 5" Simplex Piling. Anchor Blocks for the piling were to be placed as far back as the banks would allow, with the space between pile and bank infilled with poured concrete (*ibid*) (Figure 20).

4.9.3 Canal mania in the Lower Lea Valley

During the early 19th century the Trustees showed renewed interest in proposals for large-scale improvements to the Navigation below the Hackney Cut, and at least two canalisation schemes were published, possibly in association with the abortive London to Cambridge Junction Canal. Whereas the first of these schemes proposed a modest cut between Old Ford Lock and Bow Bridge, the more ambitious envisaged the construction of a long north-south cut between Old Ford Lock and Three Mills, which would have intersected both the 'Old River' and the western end of the Bow Back River before rejoining the Lea to the west of Three Mills (Figures 21 and 22).

Neither of these plans progressed beyond the drawing board and it does not appear that any effort was made to modify the alignment of this stretch of the Lea until later in the century. The final flourish of the 'canal mania' of the late 18th and early 19th centuries took place with the construction of Sir George Duckett's (later the Hertford Union) Canal between White Post Lane Bridge on the Hackney Cut and the Regent's Canal in 1830. Duckett's Canal was a speculative venture by its eponymous namesake, which lay without the jurisdiction of the Trustees of the Lea Navigation. Originally intended to encourage Lea traffic to use Limehouse Basin in preference to the East India Docks, Duckett's Canal did not prove to be a commercial success (Mylne, 1993 edition). Owing to the sharp fall between the Regent's Canal and the Hackney Cut a sequence of three sets of locks were installed in the lower reaches of the Canal. This section overlay the network of drainage channels that Cardwell had depicted to the west of the Hackney Cut, and the Hackney Sewer was culverted underneath it south of White Post Lane and just east of Bottom Lock. Before the 1850s this sewer then flowed south to Old Ford Lock via a channel on the west bank of the Hackney Cut (Figure 22).

4.10 The Stratford Committee

Despite the fact that the Trustees had successfully discharged their obligations to improve the Navigation, they appear to have been less effective at managing disputes between users of the waterways. By the 1820s disquiet was growing concerning the apparent inability of the Trustees and the jurors of the Conservancy Court to address the rising number of flagrant abuses of the navigation by mill owners, which had caused an increase in the frequency of tidal flooding on the banks of the Lea and the Back Rivers in Stratford. The extent of the damage caused by flooding was exacerbated by the growth of trade and industry in the area over preceding decades, and in 1825 a committee representing local businesses affected by the floods was established in order to lobby the authorities to correct the abuses and restore the navigation (CLA/047/LR/07/022; CLA/036/02/1828/4/2).

The Stratford Committee identified a number of long-standing encroachments that they considered were responsible for the floods that had caused its members “the greatest inconvenience and loss” and which they believed threatened the economic viability of the entire Lea Navigation if left unresolved (CLA/036/02/1828/4/2). The failure of the authorities to act on the Committee’s recommendations was cause for a further petition concerning the deteriorating state of the navigation, addressed directly to the Mayor and Court of Aldermen of the City of London in 1828 (CLA/047/LR/07/022).

The report and petitions, together with a map of the Back Rivers that accompanied the latter (Figure 24), offer a useful insight into the condition of the waterways and the growth of industry during the second quarter of the 19th century.

5 Development and function of the waterways: the Channelsea and Waterworks Rivers

5.1 The course of the Channelsea and Waterworks Rivers

Before the early 20th century, the Channelsea branched off the Waterworks River south of Temple Mills then headed south-east towards the Causeway (later Stratford High Street), below which it passed through Wigen/Abbey Mill, before joining the Lea below Three Mills.

A short distance south of the junction with the Waterworks River, a number of ditches joined the Channelsea from the east. The channel that entered at Potter's Ditch was the northern boundary of the detached portion of the Wanstead Slip, the south-western extremity of the parish of Wanstead, and as such almost certainly predated the 13th century (VCH Essex, 1973: 317). To the north of this another ditch entered the Channelsea at the point where the river headed west towards the Waterworks River. This channel was labelled the Leyton Common Sewer on a map of 1825/8 (CLA/036/02/1828/4/3), which showed it draining into the Channelsea at the same point where the present day Henniker's Ditch joins the river (Figure 24). It appears therefore that the Leyton Common Sewer carried surface drainage from the Leyton Levels to the north-east, and joined Henniker's Ditch a short distance to the east of the Channelsea, into which both discharged floodwater from the Levels and the adjacent marsh.

It is possible that the Channelsea between the Waterworks River and Abbey Mill was diverted from an earlier course prior to the construction of the Channelsea Bridge at the beginning of the 12th century, in order to exploit it both for tidal power and navigation. Clayton's 1821 tithe survey of the parish of All Saints West Ham reveals that the south-eastwards curve of the Channelsea from its junction with the Waterworks River towards the Abbey Mill seems to be overlain across an earlier pattern of land divisions (Figure 23). It is also possible that an earlier course of the river may have been preserved in the distinctive pattern of field boundaries to the east of the Waterworks, in which the alignment of the upper section of the river seems to continue southwards until it rejoins the Waterworks on a bend north of the London–Stratford Causeway.

During the 14th century the Channelsea River above Abbey Mill was prone to tidal flooding, and it is possible that this may have caused minor alterations in the river's course. It is likely that the increasing frequency of tidal flooding during the 14th century impeded drainage in the Back Rivers, encouraging deposition in the channels and causing the river to overwhelm existing defences. In turn this inflamed a long-running dispute between local landowners regarding responsibility for drainage and flood prevention works that continued throughout the 14th century (Barber *et al*, 2004: 36, 56).

5.2 Development and industry on the Channelsea and Waterworks Rivers

The earliest depiction of the Channelsea River, Bridge and Abbey Mill appears in 1560 on a sketch map of the Lea and the Back Rivers drawn by Elizabeth I's Lord Chancellor William Cecil, Lord Burghley, which also showed the braided channels of the Lea, the upper Waterworks and the Channelsea south of Temple Mills joining and then dividing again above Old Ford (Bull, 1958: 375; SP12. State Papers (Domestic) Elizabeth, Volume 15, No. 16).

The land on either side of the upper reaches of the river was generally set aside for grazing, though osiers were cultivated along the banks between the mid-16th and 19th centuries (VCH Essex, 1973: 74-6). By the end of the 17th century the area of the Abbey Marsh between Channelsea Bridge and Abbey Mill on the east bank of the Channelsea had become the centre of the English calico printing industry (VCH Essex, 1973: 77; ACC/2423/P/0601, plan not reproduced). In 1699 a calico printer was accused of erecting dams and sluices in the Channelsea presumably in the vicinity of the later 'Calico Ground', and was instructed to remove them. Calico printing on the east bank expanded throughout the first half of the 18th century, to become one of the major industries in the area by 1740.

The 1825 petition, which related to the abuses on the River Lea and Lea Navigation, had also affected the local businesses associated with the Channelsea and the Waterworks River. One of the signatories of the 1825 petition was a Mr Moline, owner of the Hop Ground on the north east bank of the Channelsea at High Meads, (CLA/036/02/1828/4/3). Both Chapman and Andre's map of 1777 and the petitioners' map of 1825 show the Hop Ground located close to an unidentified riverside property on the east bank of Channelsea. This structure, and a footbridge over the river, were probably associated with the Hop Ground. A short distance to the south on the west bank, a dye works was depicted on a speculative canalisation plan of c1812, though this does not appear on any other map of the period (Figure 22).

By 1828 however, 'the creek by Temple Mills communicating with the main stream' at the top of the Channelsea had become blocked, preventing vessels from entering the Waterworks and thence the Lea Navigation, rendering the river inaccessible to shipping from the Channelsea (CLA/036/02/1828/4/2, Figure 24). Clayton's tithe map of 1821 shows what appears to be floodwater in the field on the east bank adjacent to the two channels that linked the Channelsea with the Waterworks, indicating that the river had indeed breached its banks at this point, most likely as a result of an obstruction in one or other of them.

The fact that Temple Mills was derelict throughout much of the 1820s suggests that for once the blockage may have been a consequence of neglect rather than the self-interested actions of the occupants (VCH Essex, 1973: 199). It is not altogether clear whether the blockage was completely cleared, although the main channel to the Waterworks appeared free of obstruction in the Commissioners of Sewers survey of 1829 (ACC/2423/P/0601, not reproduced). However, the upper reaches of the river appear to have become increasingly sluggish and blocked thereafter, and it is possible that the navigation was never fully restored.

Away from the Saynes and City Mills sites and the south bank above the High Street, there was little development along the Waterworks River before 1850. Land on the east bank that had been owned by the Carpenter's Company since the 18th century remained undeveloped, although a bridge carrying the Eastern Counties (later Great Eastern) Railway from Shoreditch to Romford (extended to Colchester in 1843) had been built in 1839 (VCH Essex, 1973: 46, 61). Three arches spanned the river, the riverside track later known as Wharton (Warton) Road and the Great Tommy Lea Sewer, which discharged into the Horse Pond at the foot of the Waterworks River (COL/PL/01/049/B/365). The bridge was later modified in order to accommodate the widening of Warton Road and the culverting of the Great Tommy Lea Sewer during the 1880s. Between the bridge and the Horse Pond a number of dilapidated properties lined the east bank alongside the future Warton Road; these were demolished during the 1880s (COL/PL/01/049/B/356, 359).

5.3 The Channelsea and Waterworks Rivers between c1850 and c1890

Throughout the 1870s the West Ham Local Board reported that effluent from the Leyton Sewage Works was entering the upper reaches of the Channelsea, and in 1878 the Board secured an order from Chancery preventing Leyton from discharging into a channel known as the Wanstead Ditch (VCH Essex, 1973: 39, 209). This ditch is most likely to have been the northern boundary of the Wanstead Slip, which was absorbed into West Ham in 1875. The opening of the Eastern Counties (later Great Eastern) Railway from Stratford to Cambridge in 1840, and the construction of the Grange Park estate to the north-east of the line after 1860, had disrupted surface drainage in the area, and it appears that effluent from the hastily constructed sewage works was entering the river via a lower watercourse than it had done previously, although it is possible that it was also discharging via the Leyton Common Sewer/Henniker's Ditch, both of which remained open at that time. It is also likely that before the completion of the West Ham main drainage system the latter carried sewage from the Henniker's Road area of Stratford New Town, which had been built to the east of the G.E.R. Railway Works during the 1840s and 1850s (VCH Essex, 1973: 47).

In 1883 the connections between the Leyton Common Sewer, the Wanstead Ditch and Henniker's Ditch were severed, and the Sewer was diverted in order to discharge treated effluent from the recently upgraded Leyton Sewage Works into the Dagenham Brook, which in turn discharged into the Waterworks River (Figure 25; VCH Essex, 1973: 200). This was followed by the culverting or infilling of the entire length of the now redundant Wanstead Ditch before 1894-6, leaving Henniker's Ditch to discharge only storm drainage into the Channelsea thereafter.

To the south, the Carpenter's Company began to develop Carpenter's Road in the early 1860s. The road spread north-west from the High Street parallel to the east bank of the Waterworks, reaching the G.E.R London to Colchester line by 1864 (VCH Essex, 1973: 46; 84). The near simultaneous development of Carpenter's and Warton Roads opened up the east bank of the Waterworks, where previously only the short-lived Photogenic Gas Company Works had stood. Industrial development spread along the length of the road and river shortly thereafter, beginning with Boake Roberts & Co., who occupied a riverside site near the new Carpenter's Road Bridge from c1870 (VCH Essex, 1973: 78). A short distance to the south east S.H. Johnson & Co.'s chemical engineering works (established in 1876) shared the old Photogenic Gas Works' wharf with Johnson & Co.'s Saccharum Works into the 1890s, by which time most of the riverside plots were occupied (Figure 17). By the end of the 1870s the Lea Valley Distillery Co., Wilton's Candle Works and James Palmer & Co. candle and soap factory on Warton Road occupied the remainder of the river frontage above the G.E.R. Bridge. By the early 20th century the entire east bank between Warton Road and the Carpenter's Road Bridge was lined with a mixture of stone and concrete walls and wharves (ACC/2423/P/1747/2,4, not reproduced).

This industrial development was soon followed by the construction of a new residential district between the Waterworks, the railway lines and the Channelsea. In the wake of this the established network of open sewers was progressively culverted, diverted and redirected into the main drainage system in a correspondingly piecemeal manner. Nowhere is this better illustrated than in the history of the disappearance of the Great and Little Tommy Lea Sewers.

Before the 1840s the Great and Little Tommy Lea Sewers were unremarkable (and apparently nameless) channels that conveyed surface drainage into the Channelsea River from the High Meads to the east. To the south-west of the Channelsea excess floodwater from the Stratford Marsh was drained by continuations of these channels that flowed into the Waterworks River (Figure 26). The development of Stratford New Town after the opening of the Stratford Railway Works in 1847 added considerably to the load carried by

the northernmost branches of the sewers, and long stretches appear to have been culverted to the north and east of the Channelsea during the 1860s.

South of the river the sewers remained open when Carpenter's and Warton Roads were built, with the Great Tommy Lea to the north of the G.E.R. mainline and the Little Tommy Lea running alongside it to the south. The former then headed along the west side of Warton Road before joining the Waterworks at the Horse Pond, whilst the Little Tommy Lea joined the Great Tommy Lea via a culvert under the road south of the Warton Road railway bridge. In the early 1880s the Carpenter's Company planned to widen Warton Road to 40' and convert the Great Tommy Lea into a covered sewer that ran the length of the road parallel to the river. Because the sewer was already at a lower level than the road and the river (COL/PL/01/049/B/365), it was planned to use it as a storm water drain, which would take run-off surface water from Warton Road and the houses and factories to the east via a series of parallel glazed drainpipes that ran east-west underneath the road at regular intervals (COL/PL/01/049/B/361).

A couple of years later much of the northern stretch of the Great Tommy Lea between Carpenter's Road and the Channelsea was culverted after the G.E.R. acquired land from the Carpenter's Company in order to build the Carpenter's Curve and the Carpenter's Road Goods Depot at High Meads (COL/PL/01/049/B/364; 365). Much of the Little Tommy Lea between Carpenter's Road and the G.E.R. North Woolwich Line curve appears to have been culverted in association with the Lett Road development built between 1869 and 1894-6, although both its western extremity alongside the G.E.R. mainline and a peculiarly stunted stretch in the east between the North Woolwich Line and the Channelsea survived until at least 1916 (Figure 27). The paucity of documentation relating to the gradual culverting of these two sewers proved to have been something of an inconvenience to the London Passenger Transport Board when planning the Central Line extension to Stratford in 1936: the absence of reliable contemporary plans meant that it became necessary to sink boreholes in order to find the missing sewers.

The inevitable consequence of the progressive conversion of sewers into storm water drains was an increase in the volume of water discharged into the Waterworks and other Back Rivers during periods of heavy or prolonged rainfall. Although this was the only practical means of discharging excess floodwater, its success was dependent upon a solution being found to the as yet unresolved problem of the pollution of the lower Lea and the Back Rivers by sewage from *other* districts.

5.4 The Channelsea and Waterworks Rivers between 1891 and 1929

Major works were carried out by the L.C.B. in the upper reaches of the Channelsea and Waterworks Rivers during the early 1890s. These were designed to improve drainage into the main channel of the Lea.

The upper and lower reaches of the Waterworks were disconnected from one another; creating in effect two separate Waterworks Rivers. The stretch that had run south of the Bully Fence to the point at which the southern branch of the Waterworks branched from the Lea was culverted. In line with the scheme proposed by the L.C.B. in 1891, the lower Waterworks River was intended to become an element of the Stratford Back Rivers Canal system, whilst the upper stretch was shorn of many of its blocked and sluggish branches in order to improve drainage from the higher reaches of the Lea (Figure 17). This necessitated the infilling of a number of superfluous stretches of the Channelsea.

A bank was built between the east end of the Potter's Ditch, south along the east bank of the Waterworks and south-east along the east bank of the Channelsea, thereby isolating the

curved stretch of the Channelsea to the east in order that it might be infilled and a new junction created beneath it between the Channelsea and the Waterworks (Figure 15). The Channelsea above this point had been scarcely navigable for most of the preceding 60 years, so it was intentionally converted into a conduit to convey floodwater from Henniker's and other ditches into the improved upper Waterworks.

After the curve had been removed, the junction with the Waterworks above Potter's Ditch, west of the junction with the nameless ditch parallel to and north of Henniker's Ditch, was closed and the once navigable top stretch of the Channelsea was infilled. The sole connection between the surviving section of the truncated upper stretch of the Channelsea and the Waterworks above Temple Mills was therefore the non-navigable weir by-pass channel. This was infilled between 1916 and 1926, leaving a short redundant stretch to the south that came to a dead end immediately below Temple Mills Lane, which was infilled itself in 1927 (Figure 27).

Plans to create a wide 'bell-mouth' shaped junction at the point where the new southern Waterworks branched from the Lea were shelved, and the layout of the existing intersection was retained after the stretch to the north was infilled. The 1908 survey revealed that the short stretch of new bank was reinforced with timber piles, possibly of a similar specification to those specified for the proposed Pudding Mill River cut of 1908 (Plate 1) (ACC/2423/P/1747/1, 2, 4, not reproduced).

6 Development and function of the waterways: the City Mill, Pudding Mill and Bow Back Rivers

6.1 The Pudding Mill River between c1740 and c1850

In 1752 the Lefevre partnership briefly closed the tide mill at St Thomas' Mill to ensure a larger pen of water for their works at Three Mills, whilst the Stratford Distillery continued to operate into the 1770s and possibly beyond (Fairclough, 2003: 5; VCH Essex, 1973: 79, 90). After 1767 the mill was leased to a succession of tenants and sub-tenants, who used it as a paper mill, a corn mill and an oil mill until the East London Waterworks Company acquired the freehold in 1839 (VCH Essex, 1973: 90).

Almost the entire east bank above St Thomas' Mill was devoid of development before reclamation began in the 1850s and 1860s. Until that date expansion from the south was constrained by the low-lying land on either side of Marshgate Lane, particularly beside the riverbanks to the west, large areas of which were marsh and regularly inundated by tidal flooding. The petitioners' map of 1828 shows the area submerged under a semi-permanent pool of standing water possibly caused by prolonged water penning and consequent flooding above St Thomas' Mill (Figure 24). The construction of earthen embankments on either side of the river north of St Thomas' Mill during the 1850s/early 1860s permitted limited development on the east bank from c1862 (Stanford's Library Map of London and its Suburbs, 1862; VCH Essex, 1973: 84); however to the north much of the area between the river and the northern extent of Marshgate Lane remained waterlogged at the end of the 1860s (Figure 14). It was not until the banks were rebuilt around 1869/1870 that development began.

Nobshill/Knobshill windmill stood on the east bank a short distance south of the junction with the Lea. The mill was not depicted on Chapman and Andre's map of 1777, though the plot upon which it stood is clearly shown on Chapman's tithe map of 1821, and the mill itself is identified on the 1869 Ordnance Survey. The mill had been demolished by 1894-6.

The west bank above St Thomas' Mill remained largely deserted before and after the construction of the Eastern Counties Railway (G.E.R.) bridge in 1839, although an overflow for the southernmost East London Waterworks Company settling reservoir was cut into the riverbank between 1821-1828.

6.2 The City Mill River between c1740 and c1850

By the end of the 18th century Cooke and Co. Distillers was the principal tenant of the City Mills site. A plan accompanying a lease agreement of 1797 shows the distillery in the south-west corner, alongside ancillary structures such as a cooperage, a counting house and a residence for the head distiller (Figure 29 and ACC/1037/99). These buildings formed a range on the east bank of the City Mill River, facing a stable block that stood on the north bank of the Waterworks, adjacent to the Mill Tail. To the east, Spilemans Mill continued to grind corn.

The Merchant Taylors Company owned the south-east corner of the site east of the mill tail. A piggery and a range of service buildings occupied the ground to the north, standing a short distance apart from the 'bacon warehouses' on the east bank of the City Mill River where pigs were slaughtered and their carcasses cured (Fairclough, 2003: 11). This latter

block had a small dock inlet on the east bank of the City Mill stream providing access to the river. Two windmills and a malt house, which would have supplied the distillery, stood north of the ‘void ground and morasses’ at the north and east of the bacon warehouse.

Pig rearing was often carried out in conjunction with distilling, with pigs fattened on the waste generated by milling and distilling, then slaughtered and the bacon cured on site; though distillery pig farms were in decline by the time the Spilemans Mill lease was sold at the end of the 18th century (Fairclough, 2003: 8-11). The disposal of slurry from these farms presented a problem for the river authorities, and the Commissioners of Sewers forbade the owners of Three Mills from discharging waste directly into the Lea during the 1750s (*ibid*). In the absence of any identifiable sewers or outfalls at the site, it is likely that the porcine and equine waste from the City Mills was disposed of in a similar manner.

In 1805 Messrs Howard, Jewell, Gibson and Howard, trading as Howards & Sons, purchased the lease of City Mills (CLA/047/LR/07/022; VCH Essex, 1973: 77). Howards & Sons manufactured ‘pharmaceuticals, technical and toilet preparations’ at the City Mills site until 1914, although they sublet both the mill (VCH Essex, 1973: 79, 82) and the windmills (ACC/1037/103/1). Shortly after acquiring the lease, Howards began a substantial programme of demolition and rebuilding in the north and east areas of the site. The Chemical Works and ‘Laboratory Yard’ were erected in the area formerly occupied by the piggery and bacon warehouses, whilst the stretch of the north bank of the Waterworks previously owned by the Merchant Taylors Company was extensively rebuilt (ACC/1037/99). A cofferdam was built in the river east of the mill tail, which was infilled and the existing bank to the east straightened and rebuilt in stone, providing new wharfage for the works (ACC/2423/P/1747/2, not reproduced). This was completed between 1805 and 1860, and riverfront capacity was further increased by the construction of a dock at the southern end of the new Chemical Works a short distance along the bank to the east (COL/PL/01/049/B/352). The partners of Howards & Sons were signatories to both the 1825 and 1828 petitions, and given the extent of their dock and wharf frontage it is easy to see how their business may have been affected by both the delays caused by the closure of the Bromley tide gates and the flooding of the Back Rivers that ensued.

Redevelopment on the east bank of the City Mill River was less extensive than elsewhere on the City Mills site, although the inlet near the former bacon house was infilled and the bank adjacent to the Laboratory Yard appears to have been rebuilt and lined with trees. The bank was surveyed in 1908, revealing that timber revetment stood at the waterside, behind which a stone or timber wall stood further back, protecting the Laboratory Yard itself (ACC/2423/P/1747/2, not reproduced). The land on the east bank above Howards remained vacant into the 20th century.

On the west bank, the gardens that had overlooked the distillery were retained, and both they and the footbridge that linked them to the east bank were still in use in 1869. To the north of the bridge the west bank was devoid of development, with the sole exception of J.P. Murphy’s Tar and Turpentine Distillery, which was established in 1818 on the east side of Marshgate Lane, north of the future Eastern Counties (Great Eastern) Railway bridge (VCH Essex, 1973:80). Murphy’s constructed a stone-built wharf along their river frontage, which was still being used in 1908 by Smith Bros, who occupied the site from 1866 (ACC/2423/P/1747/2, not reproduced). This wharf was demolished during the 1930s when the stretch of the City Mill River above the railway bridge was widened to 65’ as part of the Flood Relief works of the 1930s (HLG/50/57).

6.3 The Bow Back River and Stratford High Street between c 1740 and c 1850

Stratford High Street and the Bow Back River to the north were the main foci for industrial development in the period before 1850, so it is not surprising that a number of the petitioners were based there. In addition to those already mentioned, these included the confectioner John Volckman and the lime kiln magnate and local dignitary Thomas Meeson, both of whom had good reason to complain about the damage to trade the delays at Bromley tide gates caused (CLA/047/LR/07/022; VCH Essex, 1973: 78, 79).

A number of the earliest businesses in the area were located on the High Street between Marshgate Lane Lock and Bow Bridge, including Thomas Frye's Bow Porcelain Works between 1749 and 1776 (VCH Essex, 1973: 79). A more durable concern was Thomas Meeson's lime burning and cement works, which was situated on either side of the High Street and the river. Meeson's works were founded before 1839 (VCH Essex, 1973: 85), and his involvement with the 1825 Committee suggests that it was probably trading a good deal earlier (CLA/047/LR/07/022). A dock inlet and wharf were built at the eastern boundary of the works on the south bank of the river between 1825 and 1869, although the dock was infilled in association with the limited canalisation of the banks of the river between Bromley Lock and Marshgate Lane Lock in the early 1890s. An outlier of Meeson's works stood on the north bank of the Bow Back River, situated on the north side of an inlet that may have been the original mouth of the Old River, the surviving southern stretch of which still drained into its south-west corner until both were infilled at the beginning of the 1890s.

Elsewhere on the largely undeveloped north bank, the by-pass weir and flood channel that flowed between St Thomas' Mill and the north-east 'corner' of the Bow Back River was infilled, and probably culverted. This was almost certainly accomplished between 1829 and 1834 (Figure 30).

To the east of Meeson's works on the south bank stood Barsham, Lonsdale & Co. Emery Works, which was established before 1839 (VCH Essex, 1973: 85). The west bank of the short stretch facing the old Marshgate Lane Lock was rebuilt in brick or stone between this date and 1869, although it is likely that it was demolished before the entire stretch was infilled in advance of the excavation of the new Bow Back River cut in 1935 (ACC/2423/AL/091, not reproduced).

6.4 The City Mill and Pudding Mill Rivers between c 1850 and c 1890

The east bank of the City Mill River above Howards and Sons remained devoid of development during the remaining decades of the 19th century. As Carpenter's Road and Marshgate Lane had made industrial expansion along the Waterworks and Pudding Mill Rivers possible, so the absence of a comparable highway prevented development from gaining a foothold between the City Mill and the Waterworks Rivers.

The construction of the Northern Outfall Sewer embankment by the Metropolitan Board of Works (MBW) between the Lea and the High Street in 1860/1 created a physical barrier to development along both banks. In advance of construction the MBW purchased a swathe of land from the Bridge House Estate that cut across the north east of Howards & Sons and through the former Saynes Mill site, which remained for the time being in the hands of the East London Waterworks Company (COL/PL/01/049/B/352). Structures on both sites were demolished and the banks of the Waterworks either side of the sewer crossing were rebuilt in concrete or stone (from 1908 sections: ACC/2423/P/1747/2, not reproduced). Shortly afterwards Howards took over Saynes Mill, clearing the entire area between the sewer

embankment and the railway line by 1892, which was turned over to cricket pitches and allotments that remained in use after the First World War (Figure 17).

Development along the west bank of the City Mill River and the east bank of the Pudding Mill River became possible after the rebuilding of the latter between the 1850s and early 1870s. Initially, earthen embankments were built on either side of the river extending north from St Thomas' Mill towards the G.E.R. bridge, which enabled construction of Augustus Smith & Co.'s Brush & Mat Factory on the west side of Marshgate Lane by 1862 (VCH Essex, 1973: 84) and John Alderson & Sons, rope & twine spinner, before 1870 (VCH Essex, 1973: 79-82). Slater & Palmer began manufacturing printing ink in 1882, and built a stone or concrete wharf on the west bank of the City Mill River (ACC/2423/P/1747/2, not reproduced). Further reclamation north of the G.E.R. line opened up Marshgate Lane and therefore the west bank of the City Mill River to development. Firms that set up in the area included T.H. Harris & Sons' Soap, Tallow & Bone Works, which moved there from the High Street in 1873. Harris & Sons constructed a timber-built wharf along their extensive river frontage, which was still present in 1908 (ACC/2423/P/1747/2, not reproduced).

6.5 The City Mill and Pudding Mill Rivers between 1891 and 1929

The 1891 and 1908 proposals envisaged that the City Mill River would be dredged and the banks partially rebuilt, and the intersection with the Lea simplified. The latter was carried out before 1894-6, though the other works were suspended. At least one episode of timber piling took place on the west bank, north of the G.E.R. bridge, where a stretch of plank and post banking was constructed in 1903 (MoLAS-PCA, 2005: 4.5.1). This is adjacent to the former West & Sons Rope Walk, and was highlighted on plans for the aborted improvement schemes (Figure 17).

Both the intake flume at Spilemans Mill and the dock on the north bank of the Waterworks at Howards & Sons Chemical Works were infilled between 1892 and 1894-6 (Figure 17). The former may have been culverted, and it probably signalled the end of milling at City Mills. When their lease expired in 1914, Howard & Sons relocated to Ilford, and thereafter the City Mills site was leased by the Corporation of London to a number of small business tenants, until the mill was demolished under the Flood Relief Scheme in 1932-3 (VCH Essex, 1973: 79, 90).

By 1908 the Pudding Mill River was hopelessly blocked by silt along most of its length, and must have been impassable to shipping. The 1891 scheme had proposed that a new cut be made at the junction of the Pudding Mill River and the Lea, whereby the north-eastward curve at the top of the former would be infilled and a new cut made continuing the alignment of the river towards the Lea. The proposal was resurrected in 1908 (Figure 19), and again in 1912 although it had still not been carried out by 1916. The 1908 plans were accompanied by a specification for timber piling to be used in the construction of the new cut (Figure 31). The banks of the new cut were to be excavated behind a wall of 6" x 12" x 20' timber sheet piles, interspersed every fourth pile with a 12" x 12" x 22' cast iron shod gauge pile, the whole length faced by a pair of parallel horizontal 6" x 12" timber fenders above the waterline and below bank level.

It is doubtful whether the long-planned cut was made much before work took place on the nearby Pudding Mill Lock in c1922, although it is likely that the 1908 specification was observed. However the banks of the of the Pudding Mill above the Knobshill Cottage footbridge were subject to rebuilding under the 1930 Flood Relief Act, and any *in-situ* piles encountered by the contractors are likely to have been removed prior to replacement.

Between Knobshill Cottage and St Thomas' Mill the London Power Company effectively canalised both banks of the Pudding Mill in order to improve the ingress of water into the cooling system of the Bow Generating Station on Pudding Mill Lane in *c*1928 (Figure 32). This was a major programme of works that entailed the narrowing of the channel to 22', in order to maintain a mean water level of 10.32' above Ordnance Datum the length of the waterway above the new intake, which was built a short distance to the south of the G.E.R. bridge. New banks were constructed behind interlocking reinforced concrete piles, consisting of intermediate sheet piles of 1' x 6" x 14'3" which were interleaved every sixth pile with 1' x 6" x 16'3" anchor piles, in turn tied into the bank with steel ties anchored in concrete blocks where necessary. Above the piles, reconstructed earthen banks sloped back towards the road and pathway on either side of the river.

6.6 The Bow Back River, the Three Mills Wall and the Three Mills Back Rivers between 1891 and 1929

Though not part of the 1891 canalisation programme, the banks of the Bow Back River between the old Marshgate Lane Lock and the junction with the Lea were straightened in the 1880s and early 1890s, possibly in association with the construction of the Cook's Road Bridge, which opened up the area between the Lea and the Pudding Mill River to development. This was accompanied by the infilling of all the natural and man-made inlets on both banks. The banks west of the Cook's Road Bridge were rebuilt in stone during this phase, although the southern bank appears to have been rebuilt in concrete subsequently.

7 Development and function of the waterways: the Back Rivers during the 1920s and early 1930s

7.1 Navigation issues

By the 1920s it was common knowledge that the Lea Valley was frequently subject to severe flooding, which was the result of a combination of factors:

- A lack of maintenance by the Lee Conservancy Board, who at the time were constricted by earlier Acts
- Local Councils who did nothing to control ongoing dumping of sewage into streams which fed into the Lea and its backwaters
- The abnormal building development of the outlying areas
- The construction of reservoirs higher up the Lea Valley by the Metropolitan Water Board.

A consequence of the seasonal flooding was substantial material damage and injury to the health of the inhabitants of the flooded areas. This led to the Lea Conservancy Board securing passage for the 1900 Bill, which empowered the Board to prepare a scheme to provide for the regulation and mitigation of flooding within the watershed of the river. The scheme was duly drawn up, but owing to the heavy costs involved it was not possible to proceed with the scheme (LAB 4/255).

It was not only residents and landlords based on the riverbanks but also river based industries were affected too. In June 1920, the Eastern Lighterage Company secretary sent a memo to the Ministry of Transport stating that;

'These backwaters have been navigable for many past years and have been and are of great service to the manufacturers whose factories are situated on their banks. Today they are in a deplorable condition for want of attention; partly silted up with mud; the few locks they possess broken and unusable and unless something is done they bid fair to become only muddy ditches' (MT 52/25).

He went on to state that the position was that:

'the navigation which was once easy has now become most difficult and we often get craft detained for weeks unable to get in or out or move in them subjecting the barges whilst waiting to the great and ever present risk of pilfering and even open robbery.' (MT 52/25)

There was incentive to appease the Eastern Lighterage Company as at the time it owned a fleet of 19 barges, each having a carrying capacity of between 60 and 70 tonnes, all of which were involved in the passage of goods on the Thames, the Lea and the Backwaters. They carried goods for 7 manufacturers: the Sugar Malt Production Co. Ltd, A. Boker Roberts & Co. Ltd, Palmer & Co., Gospo Ltd., French Asphalt Co. Ltd, A.J. Jeffery & Co., and Metropolitan Wire Spring Mattress Co., all of which were established on the banks of the backwaters. In addition to this the Lighterage Company promised that if improvements were made to the backwaters the company would be double their fleet, acting as carriers for 17 more companies: Jensen and Nicholson Ltd, Lysol Ltd, Day & Martin Ltd., London Dye Manufacturing Co. Ltd, The Saw Mills Co. Ltd, Charing Cross Electricity Works, Premier Fish Meal Company, Harrison & Barber Ltd., British Ultramarine Co. Ltd, S.H. Johnson,

George Johnson, Excel Co. Ltd., George Rice, London Varnish Co., Yardley's Ltd., Towlers, and G.M. Judd.

In answer to the complaint about the navigability of the backwaters the secretary to the Ministry of Transport stated that that:

'the Stratford unemployment Committee have for some considerable period been given attention to the question of the relief of unemployment, and in this connection have had the under discussion the possibility of clearing the backwaters of the River Lea. They take the view that the clearance of these water-ways would afford a considerable amount of employment, and would greatly improve the prosperity of the borough' (MT 52/25).

'It is understood that these water-ways are peculiar to Stratford, and they are silted up from the want of attention. If they were clear a very large amount of trade could be carried on there, and there would be a possibility of the erection of factories on their banks, since waterside accommodation anywhere near London is now greatly sought for' (MT 52/25).

In 1928, floods in London were particularly felt in West Ham. Lt.- Col. Hon. Ben. Bathurst wrote to the Times on 19th January, stating that:

'While much attention has been drawn to the results of the recent disastrous floods in certain parts of London, little mention has been made of the damage to the other localities, notably West ham, where some 1,200 houses were flooded out. A very important factor in the problem is presented by the backwaters of the River Lee. These, formerly used as a means of transport, are now in disuse, silted with mud and have become a source of danger to public health and a contributory cause to flood. Perhaps recent events may serve to move all concerned to take due notice of the situation' (MT 52/25).

In reply to his letter the Chairman of the Conservancy Board, Sir Edmund Barnard, answered:

'We as the Lee Conservancy Board, although fully cognizant of the Danger and harm which the present situation creates and of the imperative need for action in the direction of cleansing these backwaters and rendering them properly navigable, are absolutely powerless because, although we possess nearly every other authority over these rivers, we lack the essential statutory power to levy charges, dues, rates out of which the cost of the necessary works could be defrayed' (MT 52/25).

7.2 Pollution of the back rivers

The 1800s cholera epidemics, which had affected the whole of London, highlighted the need for drinking water to be kept separate from sewer systems. The Lea was one river that was in the service of both purposes, but its use for drinking water did not stop industries from dumping waste into it. By 1921 it appeared to many who lived and worked in the area that the problem of pollution in the Lea and the Back Rivers was getting worse rather than better. The continual failure of the districts to fund a unified Lea Valley main drainage system meant that existing local sewage and drainage systems were struggling to cope with an ever-increasing public demand for sanitation and water (HLG/50/49).

By June of the next year matters had not improved. Richard Tee, the Hackney Town Clerk, observed in a memo to the Ministry of Health that 'the river at times resembles an open sewer', a claim validated by tests which identified 'an excess of solids' in samples of water taken from the Lea below Temple Mills (HLG/50/49). Over the following years, local businesses, charities, and MPs petitioned the Ministry to take action to alleviate a situation that had turned the Lea into what Sir Edward Cadogan of the Eton Mission described as 'one black clotted mass of sewage' (*ibid*).

In July 1923 W.H. Hammer wrote a report to the Medical Officer of Health saying that:

'I inspected the River Lee, walking along the bank from Lee Bridge to Spring Hill Clapton. The river was in bad condition due partly to sewage pollution brought down by the Pymmes Brook, partly to much decaying vegetable matter and to garbage thrown into the river. In addition to these source of pollution, the surface of the water was much contaminated with oil, which is possibly attributable to the works on the Middlesex banks, where oil is handled in steel barrels. Another possible source is boats propelled by oil fuel. The oil, as well as covering much of the water surface fouls the foreshores and flotsam accumulating at the water's edge. The water is in state, which makes it absolutely unfit for bathing, and at least very unpleasant for boating. A marked somewhat offensive smell was observed as coming from the Lee, where accumulation of felted scum occurred. The nuisance is thus of a threefold character:-

- 1. The sewage effluents received into the Lee, which, inter alia, give rise to offensive deposits in the bed of the river. These get detached and buoyed up by gas, and add an offensive item to the flotsam which is the main source of nuisance.*
- 2. Vegetable and other debris thrown into the River from boats and the bank.*
- 3. The oil referred to above.*

The remedy consists in better supervision for the prevention of these sources of pollution, for which the necessary powers should be provided. If the surface of the River could be screened at suitable places, the most objectionable part of the nuisance would be by this means be removed.' (RAIL 845/107, Vol. 46, No 18: 210)

Pymmes Brook proved to be an ongoing issue. In February of the next year a letter from the County Engineer and Surveyors Department read:

'If the discharge of trade waste into the surface water drains can be prevented, a great improvement may be effected, by the drainage from streets, houses and backyards from a populous district such as Tottenham, cannot be of a very satisfactory character, particularly after prolonged spells of dry weather. This drainage ultimately finds its way into the canalised and therefore sluggish sections of the River Lee, which acts as a Catch pit for solid matters ... It may be that some improvement in the River Lee could be effected if more frequent dredging operations were carried out.' (RAIL 845/108, Vol. 47, No.3: 42)

By September 1925 the Pymmes Brook had been partially culverted in the Tottenham area along the whole length of Angel Road. The source of most of the of the contamination which affected the Lea below Tottenham to Bow Bridge appeared to come from the Tottenham Gas Works, where an open ditch entered the Lea Navigation unaltered. A report on the condition of the Lea by W. H. Hammer in July of the same year described the River Lea in terms that left the reader in no doubt that the conditions which faced residents around the river were vile. The Lea Navigation was described as having:

'an oily surface with rising and floating lumps where it passed alongside the Gas Works at Angel Road. Surface life was observed on the water, but the oil was noticed to rise as if from a putrefying bottom. It was observed that tar dropped into the stream from a bridge used to carry a light railway for tar trucks. A sample of water taken from an effluent ditch on the east side of the Cambridge line was (although not offensive or deaerated) very yellow and turbid ... Analysis showed the water to be contaminated with sewage or trade effluent of similar character, the former being more likely. The brown turbidity noticed was due to iron. Below the point where the railway crosses the Angel Road, Pymmes Brook is dark and distinctly not clear, and analysis of the water showed it to be contaminated with sewage effluent, in fact, it was probably mainly more or less putrefied sewage.

A further ditch which, on previous visits, was not seen, but which work in progress on the road way has laid bare, comes from northwards and runs roughly parallel to the navigation. This was black and foul with much sewage fungus. It was obviously mainly sewage, which had undergone very slight treatment.

The Lee is very foul indeed from Tottenham downwards, as indeed it has been on every occasion I have been there since 1917.

The Conservancy dredger "Hercules" had been working in the lock cut, and this had probably reduced the amount of bubbling, but the water towards the south bank was covered with greasy bubbling scum and a slight bitter smell was perceptible...

My general impression, supported by analyses, was that the condition of the Lee Navigation below Tottenham Lock – the only stream available for dwellers in North-east London for boating – was in a very foul condition, which must inevitably become worse if normal summer weather continues. It is certainly unfit for boating and for the illicit bathing, which I have frequently seen, and instead of being natural pleasing feature, is an eyesore.' (RAIL 845/109)

While acknowledging the seriousness of the complaints, the Ministry of Health was reluctant to step into an area that it believed remained the jurisdiction of the L.C.B. The latter body had in fact overcome its traditional aversion to litigation and sought to prosecute local authorities that it identified as polluting the Lea and its tributaries on a number of occasions, taking action against Enfield UDC in 1921 and Finchley UDC in 1923 (HLG/50/49; HLG/50/52).

Once an unfortunate legal technicality (which meant that the L.C.B had *not* been entirely responsible for the prevention of pollution since 1900) had been resolved (HLG/50/52), the offending boroughs capitulated and started taking measures to improve sewage disposal and to clean up those watercourses worst affected by pollution. Within the boundaries of the present Olympic development area, surveys conducted by the Ministry of Health identified that the problem was at its worst in the upper reaches of the Waterworks River, which was described as being '*almost stagnant and bubbling with the evolution of gas*' and in the Dagenham Brook, which contained '*sewage in the state of septic decomposition*' (Dr J.A. Glover, August 1922, HLG/50/49). Shortly thereafter, Leyton UDC applied to the Treasury for a grant of £4000 to clean out these waterways. Later that month Glover observed that work had started at the top of the Waterworks, where he noted the presence of lime and a strong smell of ammonia (*ibid*).

8 Development and function of the waterways: the 1930s

8.1 The 1930 Lea (Flood Relief) Act and the redevelopment of the Back Rivers

Despite the improvement in the condition of the rivers that followed the remedial measures taken by the local authorities, the pollution problem that had bedevilled the Back Rivers during the early 1920s re-emerged towards the end of the decade, convincing senior figures at the Ministry of Health of the necessity of undertaking a programme of flood prevention works ‘which would straighten the course and increase the gradient’ of the major channels that drained the Lea Valley (Dr H.T. Calvert, November 1929, HLG/50/50).

In fact, by the time Calvert was writing, J. Mackworth Wood, a Consulting Engineer retained by the L.C.B., and W. Lionel Griffiths, Borough Engineer of the West Ham Corporation (ACC/2423/AL/104), had already devised such a programme. Building upon a scheme that the L.C.B. had floated, then withdrawn in 1921, Wood and Griffiths proposed a plan that would provide flood drainage for the entire Lea Valley, reducing the incidence of flooding caused by upland water entering the Back Rivers, and which would allow selected Back Rivers to be navigable irrespective of tide (W. Lionel Griffiths, 12th November 1929: ACC/2423/AL/104). A provisional costing of the scheme, covering such expenses as compensation for lost water rights, land and building purchases, produced an estimated total of £550,000 in December 1929. Buoyed by a tide of professional and public enthusiasm, the L.C.B. sought Parliamentary powers to implement the scheme in November 1930. The scheme (ACC/2423/AL/104) consisted of two main elements:

- The Main Drainage River, a single flood channel starting below Carpenter’s Road Bridge and continuing to Three Mills. This would entail widening the Waterworks River to 100’ between Carpenter’s Road and Stratford High Street, and the Three Mills Wall River below that. Both would be straightened and where necessary diverted. A new road bridge was to be built to convey Stratford High Street over the Waterworks Flood Channel (HLG/50/57), and the opportunity would be taken to widen the High Street to 100’. The sides of the new channel would be protected by piling and concrete flood walls, and additional culverts would be made under the L.N.E.R. (former G.E.R.) railway bridge and the Northern Outfall Sewer bridge in order to allow the increased volume of floodwater to pass underneath (Figures 33- 35, Plate 3).
- The Canal System, which would consist of the City Mill and Bow Back Rivers, both of which would be widened to 50’ – 65’ and connected to the Lea via a new cut above Stratford High Street in order to make them navigable at all times. These were to be connected to the main drainage channel by new locks at Carpenter’s Road and at the City Mill that would maintain the water level throughout the canal system at 10.32’ above Ordnance Datum, the same level as the Navigation (see Plates 4 & 5).

Certain elements of the existing waterways would be made redundant by the scheme; it was planned to infill the entire length of the Three Mills Back River and a section of the Pudding Mill below the new Bow Back River Cut. The Channelsea was excluded from the scheme, ‘on account of cost and the small advantage to be gained in disposing of flood water’ (J Mackworth Wood, n.d., ACC/2423/AL/104, not reproduced). The cost of re-opening the river to navigation above the High Street was considered prohibitive, so it was suggested instead that the local unemployed could be put to work carrying out a limited programme of bank and riverbed cleaning whilst Parliamentary approval was being sought for the main Flood Relief Bill (*ibid*).

As an adjunct to the main Flood Relief works, a small number of modifications were proposed for the Lea Navigation between Bow Lock and Old Ford Lock, intended to preempt the increase in river traffic that was optimistically predicted would follow the completion of the new canal system (W. Lionel Griffiths, April 1930 in HLG/50/57). These were to include:

- The construction of a new lock, sluice and river wall adjacent to the existing lock at Bow (ACC/2423/AL/087, plan not reproduced). The contract for these works specified a pitched slope of granite sets below the new reinforced concrete piled river wall, a design used elsewhere on the protective works associated with the Flood Relief scheme, including the north bank of Bow Creek (ACC/2423/P/2544, plan not reproduced) and a stretch of the east bank of the Lea (MoLAS-PCA, 2005: 4.6.10). Granite coping for the lock was to be acquired from Carnsew quarry, near Penryn in Cornwall, whilst it was permitted to use second-hand granite sets for the river walls. Completed in 1931, these works were amongst the earliest carried out under the Act.
- The deepening and dredging of the Lea between Bow and Old Ford Locks, and the reconstruction of banks and towing path walls where necessary. Work carried out under this contract, probably in accordance with a similar specification to that issued for towing path reconstruction in the Hackney Cut, and is likely to account for a number of the stretches of steel and concrete piling along the Lea.

8.2 The Main Drainage River

Under the 1930 Act, programmes of work were awarded to contractors on a tender-by-tender basis, resulting in a series of discrete construction episodes, each of which was completed between 1931 and 1935 (HLG/50/57). The conversion of the Waterworks and Three Mills Wall Rivers into the Main Drainage River consisted of four phases:

- The first phase started with the widening of both banks of the Lea below Carpenter's Road Bridge in order to create the 'bell-mouth' entrance to the Waterworks originally proposed in 1891. The banks here were rebuilt in concrete over pre-cast concrete shuttering, a technique also used at the new Carpenter's Lock and elsewhere (MoLAS-PCA, 2005: 4.6.8).
- The second phase consisted of the widening of the Waterworks River on its western side and parts of the eastern side from the junction with the Lea, and the construction of high concrete banks that terminate south of the L.N.E.R. bridge.
- The third phase entailed the diversion of the Waterworks, the tail of the City Mill and the Three Mills River below the L.N.E.R. bridge, and the widening of both rivers to 100'. The central stretch of this phase, a contract awarded in its own right, is illustrated in Figure 34.
- The fourth and final phase of the conversion comprised widening the east and west banks of the Three Mills Wall River, terminating at the Three Mills Distillery.

8.3 The Canal System

The confluence of the Lea and the City Mill River was widened on the east bank in a similar manner to that used at the top of the Waterworks River. Next, the east bank of the river was widened as far south as the L.N.E.R. bridge, as were certain stretches of the west. A high concrete bank with slight batter was built along the east bank. Separate contracts were issued for the widening of the east and the west banks between the railway bridge and the Northern Outfall Sewer embankment.

The Bow Back River diversion commenced at the City Mill Tail, creating a new channel between the base of the City Mill River and a point 7.7 chains east of the Cook's Road Bridge. Separate contracts appear to have been issued for the cut and the river walls, which were built in 1935 (ACC/2423/AL/091). The contract for the protective works specified that any existing walls encountered were demolished, and that the contractors were to erect a combination of mass and piled concrete walls along the new cut (*ibid*).

8.4 The New Locks

A new lock was constructed at City Mills between the Waterworks Main Drainage River and the City Mills River Canal in 1932 (Figure 33, Plates 4 and 5). A single chambered lock with two sets of gates was built, and both gates and lock furniture are illustrated in Figure 57. Above the lock a new lock-keeper's cottage was built, which stood on an island formed by the City Mill Canal, the lock channel and the sluiceway to the east, which served as the by-pass channel and weir between the two waterways (HLG/50/75).

The Carpenter's Road Lock and sluiceway were built a short distance to the south of the rebuilt junction of the Lea and the Waterworks Main Drainage River. The lock was designed both to maintain a constant level within the canal system and as an element of the flood protection system. In accordance with the latter role it was vital that gates of the new lock were high enough to direct floodwaters along the course of the Waterworks, and a unique design of rising radial gates was selected for the task.

8.5 The 1938 Lea Conservancy Catchment Board Act and other post-war works

Under the Land Drainage Act of 1930, responsibility for surface drainage in the area was finally wrested from the hands of the near-moribund Havering and Dagenham Commissioners of Sewers, and given instead to the newly constituted Lea Conservancy Catchment Board (VCH Essex, 1966: 75; VCH Essex, 1973: 200). The new board was made up of members of the L.C.B., the Ministry of Agriculture, and Essex and Middlesex and Essex County Councils, and in 1934 began to explore how it could further alleviate flooding in the Lea Valley. During their investigations the L.C.C.B. commissioned a survey of the banks of the Lea between Carpenter's Road Lock and Temple Mills (Figure 35), which was to form the kernel of the flood prevention scheme proposed by the 1938 Lea Conservancy Catchment Board Act.

The scheme proposed widening and deepening the Lea between Carpenter's Road and Temple Mills, demolishing the Temple Mills Road Bridge, infilling the surviving northern stretch of the Waterworks River and culverting the remaining exposed stretches of the Leyton Common Sewer and the Dagenham Brook (ACC/2423/AL/098, not reproduced). The Second World War delayed the implementation of the scheme, and work finally commenced in 1950, running on in some areas into the 1960s (AN/13/417).

8.5.1 Widening the River Lea

It was planned to widen the channel of the Lea to a bed width of 90' - 100' (c.27-30m) including flood protection works and banks, between the Victoria Park Branch Railway bridge in the south to a point 320' south of Temple Mills. Above the confluence of the Lea and the Waterworks, 1,425' (c.434m) of flood banks and a 740' (c.225m) sloped concrete wall were to be constructed, with a level beam at the top of the channel (Figure 36) (ACC/2423/AL/091). These works were completed during the early 1950s.

8.5.2 *Infilling the Upper Waterworks*

The entire length of the Waterworks between Potter's Ditch and the Dagenham Brook was infilled. Groundwater drains were laid in the bed of the former channel, and 1,000' (c.300m) of surface water sewers were also placed there in order to collect the land drainage discharged into the former river from the old Dagenham Brook and other channels to the east.

The remaining open stretch of the Dagenham Brook along Temple Mills Lane was to be culverted, as were any sections of the Leyton Common Sewer that were still open.

8.5.3 *The Channelsea*

The 1938 Act also proposed the construction of a "new channel in earth" between the improved channel of the Lea and the Channelsea at the junction of the Lea and what remained of the northern stretch of the Waterworks; i.e. at the former Bully Fence. This channel was not dug in the 1950 round of works. However, when the remaining stretch of the Waterworks between the Bully Fence and the 1890s Channelsea/Waterworks junction to the north was culverted later in the 1950s, the opportunity was taken to excavate this long-planned channel, which seems to have been completed at some point between 1961 and 1974.

The final stretch of the Channelsea to be culverted before recent works commenced was the stretch between Stratford High Street and Lett Road, which was covered in 1957/8.

The waterways were changed hugely by the works, a change illustrated by comparison of a 1930s photograph of the rivers (Plate 6) with earlier maps of the area.

9 Development and function of the waterways: the impact of the railways on the canals

The latter half of the 18th century was the golden age of the canals, when transporting goods by waterway took off and investors made great profits from canals running through areas of heavy industry. Sadly though (for the waterways and the people who had invested their savings in them) the advent of the railways in the nineteenth century was to have a massive impact on the waterway transport network. Profits dropped and many canals fell into neglect and disrepair.

The arrival of the railways in the 19th century and the building of the extensive Railway Works to the north-east of the current North London Line, led to the rapid growth of Leyton and the construction of housing to the north of the former Great Eastern Railway.

By the mid-19th century, the Great Eastern Railway (the main London to Stratford line), the North London Line and the Northern Outfall Sewer had been constructed across the area of the Olympic development site. Their bridges became an essential component in the character of the waterways. These infrastructure features along with the waterways divided the Olympic site into separate areas, which developed differently from one another, creating zones with distinct characters. Thus the area between the High Street and the Bow Back River and the triangle of land between Blaker Road and the Northern Outfall Sewer were already built up, with dense industrial development, by 1870, while the areas to the north remained sparsely developed – the Bow Back River acting as a barrier to development. The course of the waterways on the historic Ordnance Survey maps of 1869 (Figure 14), 1896 (Figure 15) and 1916 (Figure 27) show a number of dock-inlets off the main waterways around the area of the Bow Back River. These appear to decrease in size, presumably due to silting, throughout the 19th century, suggesting that these inlets were earth banked or had relatively light timber revetments. There are also a number of similar dock-inlets leading off a now extinct river between the River Lea and the Lea Navigation, this being in-filled before 1916 (Figure 27).

The 1840s saw a rapid expansion in railway construction. Railway companies, such as the Midland, the London and North Western, and the Manchester, Sheffield and Lincolnshire were set up in 1844, 1846 and 1847 respectively. The railways quickly gained public support as they could break the monopoly of the waterways by reducing their tolls. The increased speed that railway transport allowed meant that manufacturers could store less raw materials and make better use of capital. People could travel further and faster than before enabling them to sell goods, recruit labour and exchange ideas rapidly. Against the railways, the waterways were weak; various factors and features of the canal system helped to both marginalise the inland waterways and to assist their competitors, the road and rail networks. These included the following:

- There were many different independent waterway owners, who often pursued mutually hostile policies.
- There was no national gauge for waterways, with the result that the canals and canalised rivers varied in width, lock dimensions, tunnel size and bridge headway.
- Transshipment was frequently necessary and there were no through tolls.
- The early years were full of haste and public excitement; in consequence, there were some cases of poor construction, bad management and ill-devised schemes, which lead to inferior routes and underestimating of capital costs.

- Little attempt was made by the carriers to adhere to the regular time-tables.
- In winter, stoppages arose through ice or floods, and in summer, drought could interfere with traffic (LAB 101/79).

Many waterways sold out to railway companies, who wanted control of them for several reasons: firstly to silence opposition to their own business, secondly to thwart competition, and thirdly to build their own lines along the courses of the canals. The 1845 Canal Carrier Act allowed canals to lease each other, including railway-owned canals. By the end of the 1850s railway companies controlled a considerable mileage of the waterways in Britain and were not about to encourage canal traffic. This led, naturally, to the mismanagement and abandonment of some waterways, triggering the passing of Acts such as the 1873 Act to safeguard canals.

In the battle between independent waterways and the railways, the main weapons of the waterways were toll reductions and their own carrying fleets. Fly-boats were put on to give rapid delivery times, steam tugs appeared on lock-free stretches, and opening hours of locks were extended, making the working hours of the lock keepers longer and harder. This issue would remain an ongoing one for waterways workers, and would come to a head during the late 1940s and early 1950s.

Despite their obvious advantages, railways did not end canal freight and the waterway technologies that had been developed in the early 18th century continued in use for commercial purposes right up until the 1960s. By this time, most boats had been fitted with engines, but horses were still a common sight on many towpaths – particularly along the narrow canals (Figure 37).

10 Development and function of the waterways: the impact of the Second World War

10.1 Preparing for war: 1936-1939

10.1.1 Control of the waterways: 1936-1939

As the threat of hostilities with Germany grew during the mid-1930s, officials at the Ministry of Transport began to explore means by which the transport infrastructure of the British Isles might be harnessed in order to most effectively serve the national interest. Of the principal modes of transport, the inland waterways had long been considered to be the least significant, and since the beginning of the 20th century a succession of Royal Commissions and Departmental Committees had discussed how to manage their seemingly inevitable decline ('Planning for Post-War Reconstruction – Canals' Z11/206 n.d. MT 52/112).

In contrast, the importance of the railway network to the national interest had been recognised at the outbreak of the First World War, when the railway companies and the railway-owned canals were taken under *de facto* state control for the duration of the conflict. It was only after the independent canal undertakings implored the Board of Transport to extend this control to all waterways that the government relented, and in 1917 23 canals (excluding the Lee Conservancy, which remained independent) were taken under control in order to relieve pressure upon the rail network by taking heavy and bulky non-urgent traffic ('Work of the Central Canal Committee', n.d. MT 52/112; MoT Internal War Book: Inland Transport, n.d. MT 52/41).

Given the widely-held perception that the waterways had continued to decline during the inter-war years, it was considered unlikely that the government would need to assume control of the canal network during a future emergency, at least during the early stages of conflict (MoT memorandum 23/09/36, MT 52/41).

By 1938, against the background of rising tension between the Western Powers and Germany, the Ministry concluded that '*the most complete Governmental direction of the national effort would be necessary*' in the event of all-out war, and departmental officials set about developing plans for the central co-ordination of all transport resources, including the independent inland navigations (MoT memorandum 22/04/38; MT 52/41). Conscious of the dramatic decline in traffic and crippling labour shortages that had afflicted the waterways during the previous conflict, the canal undertakings were eager for guarantees of government support in the event of war, and in June 1938 S.R. Hobday, General Manager of the Lee Conservancy informed the Ministry that both the Canal Association (the representative body of the canal undertakings) and the National Association of Canal Carriers were in favour of some sort of government control (MoT memorandum 28/10/38; MT 52/41).

The following year, emergency powers that permitted the government to direct the inland waterways in the national interest were formalised by Act of Parliament. The Emergency Powers (Defence) Act 1939 granted the Minister of Transport authority to ensure 'that public utilities undertakings, including canals and inland navigations are carried on in such a manner as he thinks proper in the interests of the public safety, the Defence of the Realm or the efficient prosecution of the war or for maintaining [essential] supplies and services' (CDAC Minutes of the 1st meeting, 12/09/39 MT 52/44).

While it was planned to once again bring the railways and railway-owned canals under government control, leading figures at the MoT remained opposed to the assumption of state control of the independent canal undertakings and carriers, fearing in part that financial guarantees might simply underwrite uneconomical concerns that were of little use to the war effort (MoT memorandum 29/11/38 MT 52/41; Minute sheet 06/04/42 MT 52/112).

Therefore it was decided to establish a consultative body that would 'advise the Minister upon measures to secure the best use of Canals in the National Interest in times of war' (MoT memorandum, 03/39 MT 52/41). Known as the Canal (Defence) Advisory Committee (CDAC), the new body was appointed with special responsibility to ensure that the 'heavy burdens which will be placed upon railways, restriction of road transport and the clearance of ports, in particular those affected by the diversion of shipping' be more equally shared by the inland waterways (CDAC Articles of Association, MT 52/42).

10.1.2 Civil defence of the waterways

The Civil Defence Act 1939 required that the canal companies undertake a series of Air Raid Precaution (ARP) measures in order to protect both personnel and property from aerial attack, and placed particular emphasis upon the need to make special provision to protect 'vulnerable points' (VPs) on the inland waterways (MoT Minutes, 26/07/39, MT 52/41). In addition, the canal undertakings were expected to ensure that employees were trained and available to carry out part-time Civil Defence duties in order to support local authority ARP personnel (File ARP GEN 485, HO 186/2201).

Collective protection for canal employees and barge crews was to be provided in the form of shelters established at key points on the canal system (ARP Memo C7 1938; MEPO 2/3592). During the summer and autumn of 1939 the Lee Conservancy Board purchased 12 steel air raid shelters to provide protection for personnel at Bow, Old Ford, Lea Bridge and Enfield, while resident employees such as lock keepers and their families were issued corrugated steel Anderson shelters free of charge by their local authorities (LCB Minutes, Vol. 62 No. 12: 173. RAIL 845/123).

Home Office instructions for the protection of VPs on the canal network, including reservoirs, lock gates, sluices, weirs, bridges over canals, pumping stations and embankments, were issued in 1938 (ARP Memo C7 1938 MEPO 2/3592). Measures specified for the protection of lock machinery from air attack included covering machinery hatches with layers of sandbags interleaved with tarpaulins, and keeping one set of lock gates open when the lock was not in use (*ibid*). In accordance with these instructions the LCB identified and took measures to protect key waterway VPs, including the locks at Bow, Old Ford, and Enfield, where walls of sandbags were erected around the gates and gearing (LCB Minutes, Vol. 62 No. 12: 174. RAIL 845/123).

As well as protecting essential plant, canal undertakings were advised to secure adequate supplies of spare parts for machinery and to store planks and timbers for dams at locks. During the autumn of 1939 CDAC set aside a bulk allocation of imported softwood for the use of canals and carriers (CDAC 5: Memorandum for the 2nd meeting 'Control of materials', MT 52/45), and by October of that year the Board had acquired sufficient quantities of timber to establish stockpiles for use in emergency at Bow, Old Ford and Enfield locks (LCB Minutes, Vol. 62 No. 12: 174. RAIL 845/123).

The Board also organised regular foot patrols of the banks of the Navigation and Main River, and established emergency repair squads ('stand-by gangs') stationed near VPs where they could be swiftly deployed when required to keep communications open and prevent flooding in the event of air raid damage (*ibid*). ARP procedures for the protection

of the waterways evolved as the war progressed; in some cases they were relaxed (for example, daytime foot patrols ceased at the beginning of May 1941 as the threat of invasion receded), whilst in others they were enhanced, as in the case of the establishment of a permanent night patrol at City Mill Lock the same month, which took place in response to the increasing scale and ferocity of night-time air raids that spring (LCB Minutes, Vol. 64 No. 5: 64. RAIL 845/125).

In order to comply with Defence (General) Regulation 25 (3) 1939, the Board was also required to make provision for the cleansing of vessels contaminated by aerial gas attack. Instructions were issued to Lee Conservancy staff at Bow, Limehouse and Old Ford Locks to admit local authority ARP personnel to decontaminate canal vessels in the event of such an attack, while facilities (typically stocks of sandbags) for dealing with incendiary bombs (IBs) were also provided at these locations.

Although the Board's decontamination procedures met the standard required by the Regulations, other canal companies (such as the Grand Union Canal) established and manned their own decontamination and treatment centres, which prompted an amendment to the Defence Regulations (Controlled Canals (Decontamination) Order) 1943, obliging all canal companies both to carry out and pay for decontamination themselves (Proposed extension of powers confirmed by Defence Regulations 25 (3) 1939, HO 186/1374).

10.1.3 Civil defence of industry

In addition to the VPs on the waterways, a number of other key undertakings that required special protective measures, such as power stations and factories engaged in production of materials essential to the war effort, were located in close proximity to the Lea and the Stratford Back Rivers. Three of these had premises with river frontages, including the London Power Company Generating Station on Marshgate Lane (Bow Back River), Redline Glico Limited at Pacific Wharf (Channelsea River) and Carless Capel & Leonard, which owned factories on the Lea Navigation at Hackney Wick and on the Lea at Bow (VP Adviser, File 2, 1941. HO 45/25008).

Both of the latter companies were engaged in the distillation, distribution and storage of petroleum products for the Petroleum Board, while Carless Capel & Leonard also supplied 'certain essential products to the Directorate of Explosives (Ministry of Supply)', aviation fuel to the Air Ministry and 'special solvents' to the Ministry of Aircraft Production (Carless Capel & Leonard Correspondence File, D/B/CCL/4/1).

While certain key installations such as the London Docks were provided with permanent military protection from the outset, the majority of VPs in the Metropolitan Police District (MPD) were assessed and graded according to significance and vulnerability to sabotage and then granted appropriate levels of police protection. Each of the three Stratford VPs were initially graded 'A', entitling them to a permanent armed police guard. However, shortages in manpower ('Police protection of VPs in the MPD' 27/01/40, HO 45/25008) and the formation of the Local Defence Volunteers (later Home Guard) in May 1940 contributed to the downgrading of their category of protection to 'C' in 1941 (VP Adviser, File 1, 1941. HO 45/25008). Following this change in status the armed police guard was withdrawn, and thereafter members of Home Guard units recruited from amongst their respective workforces undertook to defend the three VPS (*ibid*).

10.1.4 Defence against air attack in the Stratford area

10.1.4.1 Balloon barrage

As early as 1936, the growing threat of war with Germany prompted the Air Ministry to consider the establishment of a permanent balloon barrage to protect London (Memorandum FOI (B) 17/09/36 AIR 2/1887). Towards the end of that year a retired naval officer named Keane surveyed potential balloon deployment sites in and around the capital, and a barrage comprising 450 balloons was established over the next two years (*ibid*; AM memorandum 02/09/38 AIR 2/1887). Expansion accelerated between January and September 1939 as the complement of the national barrage was increased from 1450 to 2600 balloons (AM memorandum 04/09/39 AIR 2/1887; AM Supply memorandum 25, AVIA 15/360).

The London balloon barrage was maintained from four depots, at Chigwell, Hook (Hampshire), Kidbrooke and Stanmore Park, each of which also served as Balloon Command Wing HQs ('Survey of sites for Balloon Barrage' n.d. AIR 2/1887; Osborne, 2006: 105-106). A number of permanent balloon sites were established to the east of the Lea in the vicinity of the Stratford Back Rivers, including:

- Position 104, on the triangular open space between Bisson and Leggatt Roads;
- Position 105, south of Lloyd's Shoot beside the City Mill River, entered from a road at the end of Marshgate Lane;
- Position 140 on waste ground west of the railway, just off Abbey Road and adjacent to the Adam & Eve public house;
- Position 141 beside the school on the corner of Rosher and Lett Roads, later renumbered and moved to the corner of Blyth and Gibbens Road;
- Position 142 on the West Ham School playing field south of Wycliffe Road (south of Henniker's Ditch).

The permanent balloon barrage extended northwards of Position 142, and positions were established on the east bank of the Lea in the Hackney Marshes, and further to the north-east on the Wanstead Flats (Location of Balloons, Field Scheme 'Nosecap', n.d. 1939; Amendment to Location of Balloons Lists Nos. 1 and 2, 18/05/39. AIR 16/323).

10.1.4.2 Anti-Aircraft (AA) Artillery

The earliest efforts to rebuild and expand upon the moribund anti-aircraft defences of London began in 1935, although progress was initially slow and by 1938 the majority of the Territorial Army (TA) AA units defending the London Inner Artillery Zone (IAZ) were still equipped with weapons left over from the First World War (Osborne, 2006: 98-99). There were two categories of AA defence: Heavy AA (HAA) batteries, which were equipped with 3'', 3.7'' or 4.5'' guns, and Light AA (LAA), units of which provided close defence and were therefore equipped with smaller calibre weapons (*ibid*: 99-104).

The majority of the 22 four-gun HAA batteries protecting the eastern approaches (ZE) to the IAZ were situated on open ground in locations such as the Wanstead Flats, while the southernmost battery was situated a short distance to the east of the Lea on Hackney East Marsh. At the beginning of 1939 a pair of 3'' guns of First World War vintage was also based at the Abbey Mills Sewage Works (List of Gun Sites in the London Area 9B, 04/02/39 AIR 16/323). Although none of the Stratford VPs were provided with LAA cover, at the outbreak of war a number of VPs in the wider vicinity were defended by obsolescent First World War Lewis guns mounted on the tops of buildings. VPs given LAA

protection included Bromley Gas Works (32 Lewis guns), the West Ham Power Station and the Lea Bridge Waterworks, each of which were provided with 24 Lewis guns (*ibid*).

10.2 The waterways during wartime: 1940 - 1945

10.2.1 *The decline of traffic on the waterways, 1939-1941*

By the end of January 1940 it was apparent that the inland waterways were not being effectively utilised in the national interest. In fact, returns submitted to CDAC by the Regional Canal Advisory Committees (RCACs) indicated that the volume of traffic carried by canals had fallen since the war began (CDAC Agenda for 2nd meeting, 31/01/40 MT 52/45). Before the war, the Ministry of Supply had indicated that it intended to 'leave industry to make its own [transport] arrangements', and over the intervening months industry had demonstrated a marked preference for road and rail over canal (CDAC Minutes of the 2nd meeting, 31/01/40 MT 52/45). Three reasons for the decline in usage were identified: unfair competition from the railways, the diversion of shipping from the east coast ports, and a growing shortage of labour.

The reason most often cited by canal operators for the fall in traffic was the disparity between the rates charged for the conveyance of freight by the railways and those charged by the canal carriers. While the former had been maintained at pre-war levels, the operating costs of the latter had risen, preventing them from competing for business on equal terms. In February 1940 the Canal Joint Committee, which represented the interests of the canal undertakings and the carriers, lobbied the government for financial assistance in order to help restore traffic to pre-war levels (LCB Minutes, Vol. 63 No. 4: 38. RAIL 845/124). The government responded by introducing a subsidy of 50% of the tolls paid by carriers in June 1940 (Hadfield, 1950: 238; MoWT memorandum 'Financial Assistance to Canals' 30/05/42, MT 52/112).

Though the uptake of the subsidy was uneven, it clearly helped carriers and canals to retain traffic by enabling them to quote rates that were competitive with rival forms of transport (CDAC Minutes of the 9th meeting, 14/05/41 MT 52/52).

The partial closure of ports on the east coast and the disruption to North Sea coastal shipping routes had a significant adverse impact upon the volume of traffic (particularly coal) carried by the navigations of the east and south-east of England. In 1938 the Lea Navigation had carried 1,782,063 tons of goods, nearly 50% (888,224 tons) of which was coal and coke ('Canal Traffic: 1940', MT 52/236). By the end of 1940 the volume of goods carried on the Navigation had fallen by a third, while the tonnage of coal carried had dropped by over 40% to just over half a million tons (*ibid*).

The cause of this decline was clear enough: unlike the Grand Union Canal, which provided a direct inland connection between the Midlands coalfields and the capital, most of the coal transported on the Lea was brought by sea from Northumberland to London, beyond which it was barged up to the gas works and electricity generating stations that lined the banks of the rivers between Poplar and Ponders End (Hobday, 'Utilisation of Canals for Transport of Coal to London', 22/02/40, MT 52/46). When the coastal routes were disrupted, producers and Port Transportation Officers simply transferred coal to the railways.

At the height of the Battle of Britain in late summer 1940, coastal routes between the north-east and the Thames were suspended altogether, and it was reported that none of the 100,000 tons of coal consumed each year by the North Metropolitan Power Station at Brimsdown (Ponders End) was being carried on the Navigation (CDAC Minutes of the 5th meeting, 06/09/40 MT 52/48). In response, the Lee Conservancy and the Mines Department

agreed to make use of and improve existing interchanges between rail and waterway to transfer as much coal traffic as possible to the Navigation. Coal carried south by rail would henceforth be unloaded for onward shipment by barge at new coal dumps at Old Ford Locks, Picketts Lock, Enfield Lock and Waltham Town Lock, between which up to 27,500 tons of coal could be stockpiled (CDAC Draft Minutes of the 5th meeting 06/09/40 MT 52/48; LCB Minutes, Vol. 63 No. 12: 172. RAIL 845/124).

Though the coal dumps were established, little progress appears to have been made to improve other interchanges between canal, rail and road by the spring of 1941, when Frank Pick (the former Chief Executive of London Transport) inspected the Lea Navigation during his investigation of the inland waterway system on behalf of the Ministry (Pick, 'Draft Report on Canals & Inland Waterways to the MoWT', 14/05/41, MT 52/109). Pick identified a number of instances where coal was transported by road or rail to locations on the Lea, when it would have been more cost-effective for it to have been carried by barge. These included the movement of coal by rail from Northumberland to the London, Midland & Scottish (LMS) Railway coal tips beside the Lea at Poplar, where it was loaded onto barges and shipped a total distance of less than 400 yards to the Poplar Electricity Works, a journey that could have been accomplished entirely by sea and inland waterway (*ibid*: 11). A further example of poor utilisation of facilities was the supply of coal to the Royal Ordnance Small Arms Factory at Enfield, which was transported by rail to dumps in the Lea Valley, then by road to the Navigation and finally shipped by barge to the factory. Pick noted that had the existing riverside coal dumps at Hertford not fallen into disuse, coal could have been transferred straight from rail to barge (*ibid*).

The third reason for the under-utilisation of the inland waterways was a shortage of labour, particularly amongst barge crews. Although canal companies and carriers had experienced manpower shortages during the pre-war period, since the beginning of the war large numbers of employees had volunteered for service with the armed forces. Many others had left for better-paid employment elsewhere, notwithstanding the fact that several of the canal trades, such as boatmen and steersmen were classified as Reserved Occupations (CDAC Minutes of the 3rd meeting, 15/03/40 MT 52/46). A major factor contributing towards the labour shortage on the Lea and other navigations was the pay and conditions of barge crews, which the Ministry of Labour considered inadequate to attract or retain labour in the industry (CDAC Minutes of the 7th meeting, 19/12/40 MT 52/50). The problem was particularly acute in the London area, and Hobday recognised that labour could only be retained through the payment of higher wages which the carriers could not afford to subsidise during wartime (*ibid*).

Towards the end of 1940, as the volume of traffic carried on the Lea Navigation began to recover following the reopening of North Sea coastal routes, carriers on the waterway experienced an acute shortfall in trained crews, which resulted in boats and barges lying idle at precisely the time when demand for coal was at its highest (CDAC Minutes of the 7th meeting, 19/12/40 MT 52/50). It was not even possible to transfer under-used vessels from the Lea to nearby navigations such as the Grand Union Canal, as much of the Grand Union was too narrow to allow Lea barges to pass (CDAC Memorandum 11 for the 4th meeting, 21/05/40 MT 52/47).

10.2.2 The Pick report and the reorganisation of the waterways: 1941-1942

Although it was never formally published, Pick's report was to have a significant influence upon inland transport strategy during the second half of the war. Pick recognised that a greater degree of central direction was necessary if the waterways were to better serve the national interest, so he recommended that the ineffectual CDAC be abolished, to be replaced by a new Central Canal Committee (CCC), which would represent the

reconstituted and strengthened RCCs (Regional Canal Committees) ('Report on canals & Inland Waterways by Mr Frank Pick', Digest of Recommendations 1941, MT 52/105). The latter would bear 'collective responsibility for water-borne traffic in their region', and would assume powers to supervise maintenance and operations of canals and canal traffic (Pick, 'Draft Report on Canals and Inland Waterways to the MoWT', 14/05/41: 8, MT 52/109). The MoWT duly adopted these recommendations in July 1941 (London RCAC to MoWT, 23/07/41, MT 52/105), and Hobday was appointed Chairman of the London RCC (comprising the Lee Conservancy and the Grand Union Canal) in September.

In order to arrest the nationwide decline in canal traffic, Pick suggested that uncompetitive rates could be made a thing of the past if transit tolls were capped to assist carriers, in return for which the canal undertakings would be given a financial guarantee of net revenue by the government similar to that given to the railway companies ('Report on Canals & Inland Waterways by Mr Frank Pick', Digest of Recommendations 1941, MT 52/105). The latter measure was to be contingent upon an assessment of the financial viability of the undertakings. This would identify those canals that were '*economically useless*' (such as the Stort Navigation) and therefore subject to immediate closure; those that were of use to the war effort and which ought to be encouraged to consolidate into single regional undertakings, and those that were to be allowed to retain their independent status, such as the Lee Conservancy (Pick, 'Draft Report on Canals and Inland Waterways to the MoWT', 14/05/41: 6, MT 52/109).

Pick also hoped to use an economic assessment of the canals to '*define and earmark the traffic*' best suited to each of the surviving navigations, in order that the traffic thus allocated could be better protected from diversion by unfair competition from rival forms of transport ('Report on Canals & Inland Waterways by Mr Frank Pick', Digest of Recommendations 1941, MT 52/105; 'Planning for Post-War Reconstruction – Canals' Z11/206 n.d. MT 52/112).

During the course of his investigations, Pick observed that waterway maintenance appeared to have been neglected by many of the undertakings since the start of the war, apparently in order to save money (Pick, 'Draft Report on Canals and Inland Waterways to the MoWT', 14/05/41: paragraph 39, MT 52/109). In turn this led to maintenance staff being released from the canals' service, thereby exacerbating the labour shortage at a time when such men were most needed (*ibid*). Though there were exceptions (the Lea Navigation was described as '*well-kept*'), Pick proposed that in return for government support the undertakings ought to be obliged to maintain and dredge canals to an agreed standard (*ibid*: paragraph 25, MT 52/109).

The Canal Association concurred with Pick's observations that maintenance had fallen into arrears on many navigations, although they did not entirely agree with his diagnosis of the cause, or with his proposed solution. The Association argued that the decline in standards of maintenance was caused by a combination of falling revenues and rising costs, the latter a consequence of the increased cost of maintenance and of the additional costs incurred by complying with the Essential Works Order (EWO), which had been extended to the canal undertakings in December 1941 (Z/11/102/4, 19/02/42, MT 52/112; LCB Minutes Vol. 65 No. 1 09/03/42: 21-22, RAIL 845/125). The Ministry of Labour had introduced the EWO in March that year in order to arrest a serious decline in manpower in industries engaged in work regarded as essential for the war effort.

The scheme guaranteed workers employment on the condition that any work offered was accepted, which helped to stem the loss of manpower but which the employers were expected to fund (Phillips, 1996: 36). Hoping for '*some assurance of survival at the end of the war*', in March 1942 the Canal Association objected to Pick's proposed survey, which they rightly feared would determine which canals received assistance and which would not,

and instead concluded with an appeal for a blanket subsidy worth a third of the cost of the maintenance required ('Application by Canal Undertakings for Maintenance Subsidy', 06/03/42 MT 52/112).

Unwilling to fund another subsidy to the industry with no reciprocal guarantee of improved efficiency, the Ministry of War Transport considered how it might '*supply some sort of central direction which might [speed] up canal development for war purposes*' ('Financial Assistance to Canals: Future Canal Policy', 30/03/42 MT 52/112). It was concluded that control (in the form of a conditional guarantee of net revenue for the duration of the conflict) should be extended to 'those canals and carriers which could make an appreciable contribution to the war effort' (Minutes of a meeting of the Lord President's Committee, 12/06/42 MT 52/112). The Defence Regulations were amended accordingly, and the Inland Waterways Division of the MoWT took effective control of 18 undertakings and 42 carriers from 1st July 1942. It is worth noting that it was not considered necessary to extend control to the Lee Conservancy, which remained independent as Pick had recommended.

During the deliberations that preceded the announcement of government control, it was decided to defer the contentious issue of pay and conditions on the waterways until the takeover process was complete (*ibid*). Subsequently the government established the National and Regional Joint Councils for the Inland Waterways Industry, which provided a forum within which pay negotiations between undertakings and unions could take place (LCB Minutes Vol 66 No. 12: 80, 01/10/43 RAIL 845/126). In July 1943 the London Regional Joint Council negotiated a pay rise of 2s per week for lock keepers and ancillary workers on the Lea at or below Enfield (*ibid*), while the length of the working week for Board employees was stabilised (at 50 hours in the summer and 41 in the winter) and rates for hours worked overtime were improved the following January (LCB Minutes Vol. 67 No. 1: 2, RAIL 845/126).

10.2.3 Traffic on the Lea Navigation, 1942-1945

The principle that the fullest use should be made of the inland waterways where practicable in order to reduce the burden on rail and road transport became policy in October 1941 (Z11/180, MT 52/109), and priority when allocating cargo was given to the carriage of bulky goods such as coal. The MoWT instructed that coal ought to comprise approximately 40% of canal traffic, the allocation of which was to be managed by regional representatives of the Ministries of Fuel and Power (GEN G112, 25/10/43, MT 52/113).

Following the resumption of the North Sea coastal shipping trade, the Lea Navigation was well-placed to meet its allocation. In order to ensure that coal traffic continued to be the economic mainstay of the navigation, Pick had suggested that a number of coal-handling facilities on the waterway required modernisation (Pick, 'The Lee Conservancy': 3, 31/01/41, MT 52/109), and it appears that these recommendations were taken up. At Hertford the disused coal heaps were brought back into use, and coaling operations had resumed by November 1942 ('Summary of the conclusions reached as a result of a visit of inspection to possible sites for hoisting LCs at Ware, Hertford & Cambridge, 18/11/42 ADM 1/15480).

In spite of the fact that less coal was carried on the Navigation in 1941 (483,141 tons) than in the preceding year, coal traffic still constituted over 40% of the total tonnage of goods carried. The following year this increased in both actual (to 577,349 tons) and percentage terms (to 52.33%), despite a sharp fall in the overall tonnage of goods carried ('Canal Traffic: Year 1942, MT 52/236). Irrespective of fluctuations in the tonnage of coal carried, the proportion of coal traffic carried on the Lea exceeded 45% for the remainder of the war, although even the largest quantity carried in any one year was still less than two-thirds of that carried during the last full year of peacetime (*ibid*).

Despite the presence of a number of industrial concerns engaged in the manufacture of material vital for the war effort on the banks of the Lea, including the Royal Ordnance Factories at Waltham Abbey (the former Royal Gunpowder Factory) and at Enfield Lock, the waterways were not a significant carrier of war materials during the Second World War. Consignments to or from military or Ministry of Supply establishments (such as munitions factories) were prioritised as railway cargo, as were consignments of certain materials designated as essential, including ARP stores, food and hydrocarbon oils (GEN G112, MoWT 25/10/43 MT 52/113). The inland waterways were simply instructed to prioritise regular traffic (such as coal) over individual or one-off consignments of material, in order that reliability of service to existing customers could be ensured (*ibid*).

Canal carriers did convey quantities of petroleum spirit (Minutes of the 12th Meeting of the Traffic Committee 22/09/43, MT 52/113), although it does not appear to have accounted for a significant proportion of goods carried on the Lea Navigation during the war years (MT 52/236). It is, however, quite possible that use was made of the Petroleum Board wharves at the Carless Capel and Leonard factories and the Redline Glico facility at Pacific Wharf to transfer cargoes of petroleum products to canal-going vessels for onward movement. According to Sir Osborne Mance, Director of Canals at the MoWT, carriage of dangerous goods such as explosives or ammunition was assigned only to road or rail carriers, and no provision seems to have been made for waterborne conveyance of such materials, at least until May 1944 (*ibid*; MoWT memorandum 'Handling & Conveyance of Ammunition etc on Canals or Inland Waterways', 18/05/44, CAB 75/19/45). This latter measure, which entailed the amendment of Defence Regulations so as to permit the carriage of ammunition upon inland waterways irrespective of local regulations or bye-laws, was expressly introduced in order that no foreseeable eventuality should impede logistical preparations for 'forthcoming operations', an unambiguous reference to the imminent Operation Overlord (CAB 75/19/75). It is not clear whether the need ever arose to use the Lea Navigation for the conveyance of such materials, either during the build-up to Overlord or during the remaining months of the war.

The Lea and its associated waterways do appear to have been used for the movement of at least one form of military transport during the war. Following the entry into the war of the United States at the end of 1941, large quantities of purpose-built landing craft were transported to ports on the west coast of the United Kingdom, in preparation for the anticipated invasion of Occupied Europe. Whilst larger sea-going landing vessels, such as LSTs (Landing Ship, Tank) crossed the Atlantic under their own steam, smaller vessels weighing between 6½ and 22 tons, collectively known as Minor Landing Craft (MLC) were carried on the decks of transport ships and were off-loaded at 'arrival ports' such as Cardiff and Liverpool, where they were held in pooled reserve (ADM 1/2627; ADM 179/238). In order to prevent congestion at the arrival ports it was decided to move the MLC to 'ports of destination', which could be either Combined Operations (CO) Training Establishments, or laying-up ports, known as 'suspense stations', where they would be held pending further requirements (ADM 179/238). Because MLC lacked living accommodation, a number of 'intermediate ports' were established at Portland, Portsmouth and Newhaven, at which craft could be refuelled and crews rest up overnight.

The movement of the MLCs (codenamed 'Operation Bedlam') began in summer 1942 and continued until September the following year, when new arrangements for handling MLCs came into force (ADM 1/12627). During the summer months the craft were manned by naval crews and sailed around the coast or via canals to coastal or estuarine suspense stations, such as the MLC Receipt and Despatch Unit at HMS St. Clement (Tilbury), where CO craft were maintained and repaired (ADM 1/14853; ADM 1/2627; ADM 1/15480). Though it is unlikely that the Lea and the Back Rivers were used for the transit of MLCs during the early phase of Operation Bedlam, by autumn 1942 it was clear to the Admiralty

that the coastal routes would not be passable during winter, and that provision need therefore to be made to increase the number travelling by inland waterway and other means over the following months (Plans Div (Q) Naval Staff 09/10/42, ADM 1/15480). Owing to the lack of interchanges between rival canal networks, the transit of MLC from west coast ports to suspense stations in the south-east presented naval planners with significant difficulties, and consideration was therefore given to moving craft at least part of the way by road (*ibid*).

It was concluded that it was feasible to move certain categories of smaller MLC (LCP, LCV and LCM) from arrival ports in the Mersey and the Severn by canal to interchanges where they would be loaded on to civilian road haulage vehicles, which would off-load them elsewhere on the canal network for onward transfer to suspense stations in the Thames Estuary (PD (Q) 4763/42 08/12/42, ADM 1/15480). While vessels travelling from the arrival ports in the Severn Estuary would make their eastward journey via the Kennet and Avon Canal and the Thames itself, those travelling from the Mersey would head east to the Humber and either travel via the Rivers Trent and Witham to Boston or coastwise to King's Lynn and thence via the Great Ouse and the Cam to Cambridge, from which they would be conveyed by road to be transferred to the northernmost end of the Lea Navigation (Figure 38). Potential sites for the gantries necessary to lift MLC from road to the Lea and vice-versa were inspected by representatives of the Admiralty at Ware and Hertford in November 1942, and the following month both the Director of Plans and the Commander of Combined Operations instructed that they be built (PD (Q) 4763/42, 08/12/42, ADM 1/15480).

10.2.4 Maintenance of the Navigation, 1942 - 1945

Unlike those inland navigations that were taken over by the government in July 1942, the Lee Conservancy had to fund general repairs and maintenance out of its own revenues. Despite Pick's generally positive report on the upkeep of the Conservancy's waterways, the regular maintenance cycle of the Lea and the Back Rivers was disrupted by the war, during which war damage repairs necessarily took precedence.

The partial collapse of a length of towing path wall on the Lea north of Carpenter's Road Bridge in July 1942 was attributed by Board Engineers to the shallow foundations of old river walls, which had been undermined by the scouring action caused by passing tugs, and it was feared that further subsidence might take place in the vicinity in future (LCB Minutes Vol. 65 No. 10 10/07/42 RAIL 845/125). A further stretch of towing path wall in the area duly collapsed that September (LCB Minutes Vol. 65 No. 11 02/10/42 RAIL 845/125). Because civilian building works during wartime were subject to restrictions imposed under Defence (General) Regulation 56A 1939, the Board had to obtain permission from the MoWT for the execution of any works costing more than £100 (LCB Minutes Vol. 66 No. 14 03/12/43 RAIL 845/125).

Authorisation was dependent upon the labour allocation determined by the Ministry, which often led to the delay or postponement of scheduled works. Plans approved by the Board for dredging the Navigation and renewing towing path walls north of Old Ford Lock in September 1944 were scheduled to take place 'as soon as circumstances permit', at some unspecified point after the war was over (LCB Minutes Vol. 67 No. 10, 29/09/44 RAIL 845/126). While emergency repairs were carried out as soon as was possible after damage had taken place, in an effort to keep the Navigation functioning, permanent repairs were often delayed months, or sometimes years after damage had occurred, even in cases where plant and installations had been damaged by enemy action.

10.3 War damage

10.3.1 War damage on the Lea and the Stratford back rivers: 1939 - 1945

At the beginning of May 1941 the Lee Conservancy Board undertook a periodic review of the effectiveness of ARP measures in the light of experience gained over the preceding eight months, during which London had been subject to sustained heavy aerial bombardment (LCB Minutes Vol. 64 No. 5, 02/05/41: 64. RAIL 845/125). In addition to making amendments to a number of existing procedures, members identified two broad categories of air raid damage that had been inflicted upon the navigation to date: either minor, which could be 'taken in hand in the ordinary way' by Conservancy employees, or 'of such magnitude that a major operation is required, necessitating the calling of outside help' (*ibid*).

Despite the fact that the Lea and the Stratford Back Rivers were situated in the midst of one of the most heavily bombed districts in the country (HO 199/395), by the end of the war the majority of the incidences of war damage on the waterways could be described as belonging to the former category, whilst only a handful merited inclusion amongst the latter.

The first large-scale daylight raid on London took place on 7th September 1940, when over 900 Luftwaffe aircraft attacked the capital. The raid continued into the night, when a number of IBs started fires in the Marshgate Lane area, whilst larger ordnance fell on the Thomas Tyre & Co Stirling Chemical Works in Canning Road, which was bombed again on the nights of the 21st –22nd September, 1st – 2nd October and finally the 19th – 20th April 1941 (HO 198/207).

Stratford was again hit by a daylight raid on 17th September, when IBs fell beside the Northern Outfall Sewer at Marshgate Lane. During this raid sawmills, offices and stables belonging to the Grand Union Canal were destroyed at Monteith Wharf on the Hertford Union Canal near Old Ford (War Damage Act 1943: Claim, IR 34/712), though Lee Conservancy premises in the vicinity escaped unscathed.

Within weeks, however, Old Ford Locks itself received a direct hit, which virtually demolished the centre pier (Plate 7) and caused extensive damage to the brick-built chambers of both the west (new) and east (old) locks (see Plate 8), entirely destroying the floor of the latter (LCB Minutes Vol. 63 No. 14: 193, 13/12/40 845/124; Hackney Archives, File No. 1 HA/46). The destruction was not restricted to the lock itself, and a number of buildings in the immediate vicinity including the Collector's House and the lock houses and stables belonging to the Board were also severely damaged. Because of the disruption to navigation caused by the damage, emergency repairs were soon underway and by November W. & C. French Ltd, the main contractor for much of the 1930 Flood Relief Act works, had been taken on to undertake permanent repairs. By December the central pier had been largely rebuilt and the repaired west lock was reopened to traffic on the 6th January 1941, while the more extensively damaged east lock reopened eight weeks later (*ibid*; LCB Minutes Vol. 64 No. 1: 2, Vol. 64. No. 3: 33, 1/01/41, 07/03/41, 845/125).

A number of other raids that took place during the blitz of autumn 1940 also inflicted damage upon Board property. While an HE bomb that landed on the bank of the Three Mills Wall River near Bisson Road on 27th September failed to explode (Newham War Damage Incident File), two HE bombs detonated on the towing path and east bank of the City Mill River near Marshgate Lane on 20th and 25th October respectively, and a further device fell into the Waterworks River off Warton Road on the night of the 10th (*ibid*).

At a time when falling revenues were placing great pressures upon the finances of the canal undertakings, the question was raised as to how the repair of facilities damaged or

destroyed by enemy action should be financed. In December 1940 the MoT somewhat optimistically suggested that the undertakings might consider setting up a mutual assistance scheme, whereby the latter pooled labour, materials and plant to ensure speedy repair of damage (CDAC Minutes of the 7th meeting 19/12/40, MT 52/50). While such a scheme may have proved of use in effecting rapid emergency repairs, the undertakings were more concerned about permanent repair of facilities, such as locks, which played a critical role in keeping navigations open. When the Treasury proposed that certain Public Utilities Undertakings should pay contributions in respect of damage arising out of the war, the Canal Association requested that the issue be deferred until after the war, while in the meantime the government paid for, or at least reimbursed the costs of urgent war damage repairs (Supplemental Memorandum of the Canal Association, 26/06/41, IR 34/712).

Claims for the reimbursement of the cost of repairing war damage were admitted under the War Damage Act 1943, although any works costing more than £100 remained subject to authorisation under Defence Regulation 56A, which often contributed to prolonged delays to the completion of permanent repairs or reconstruction (War Damage Claims, War Damage Act 1943, IR 34/712; LCB Minutes Vol. 66 No. 14 03/12/43 RAIL 845/125). Though the rebuilding of Old Ford Locks was completed in remarkable time, the damaged Collector's and Lock Houses remained in a ruinous state when the Board sought authorisation for their rebuilding in October 1943 (LCB Minutes Vol 66 No. 12: 80, 01/10/43, RAIL 845/126).

It had still not been granted the following March, when the Board stripped the buildings of intact timbers for re-use elsewhere on the Navigation, and it was not until September 1944 that architects were instructed to prepare plans for submission to the MoWT for approval and for the necessary licence for rebuilding to be obtained (LCB Minutes Vol. 67 No. 1087 30/09/44, RAIL 845/126). The saga dragged on into the following year, and architects' plans for the rebuilding of the three cottages were finally approved in October 1945, over five years after the buildings were bombed (LCB Minutes Vol. 68 No. 13: 111, 26/10/45 RAIL 845/127).

The Stratford waterways escaped any further substantial damage during the late autumn and winter of 1940, though night-time raids damaged a number of the factories on Carpenter's Road and in the vicinity of Temple Mill Lane in October and December (Newham War Damage Incident File).

West Ham experienced a brief respite from air raids during winter 1940/1941, though large-scale raids resumed on the night of the 8th/ 9th March 1941, when a number of the factories on Carpenter's Road were set alight by IBs (Newham War Damage Incident File; HO 198/33). The Redline Glico distillery house at Pacific Wharf was hit by two 50kg HE bombs (HO 198/46), which appear to have caused some damage to the wharf itself, which had been rebuilt only eight years earlier (Joint Committee River Lee Flood Relief Act Minutes No. 36, 20/09/33). An application for the permanent repair of Pacific Wharf was submitted to the Ministry in February 1945 (LCB Minutes Vol. 68 No. 2: 13, 02/02/45 RAIL 845/127). Conservancy property damaged that night included the Lock Keeper's Cottage at Bow Lock (Newham War Damage Incident File).

During a heavy raid on the night of Wednesday 16th /17th April, a parachute mine detonated on impact with the Waterworks River off the Boake Roberts Factory in Carpenter's Road, causing extensive Category 'B' damage to the concrete river wall (HO 198/46). The blast damage to Boake Robert's frontage was more extensive than first thought, and a report to the Board of the Conservancy indicated that the piling had been 'almost entirely destroyed' (LBC Minutes Vol. 76 No. 1: 2, 07/01/44, RAIL 845/126). Though responsibility for repairs resided with the owners (the Carpenters Company), in

1944 the Conservancy agreed to draw down the level of water in the river to allow the necessary permanent repairs to take place.

Boake Roberts was to suffer further damage during the night of the Saturday 10th /Sunday 11th May, when 500 bombers launched the most destructive single raid of the war on London. The Luftwaffe's radio direction beams which guided the bombers to their target intersected over West Ham (Mortimer, 2005: 105), ensuring that the area, although not the primary target of the bombers, was hit by the full range of explosive ordnance dropped that night. HE bombs fell on the recently rebuilt bank of the Lea beside the British Feeding Mills, a short distance from Carpenter's Road Lock, whilst a 50kg HE bomb landed in the 'River Bed Saltings' of the Channelsea, approximately 80' (c.25m) south of the point at which the Northern Outlet crossed the river (HO 198/46). Another 50kg HE exploded on the Leyton Sewer, a short distance from the Hallins Piggeries near Temple Mills, which also received a direct hit that night (*ibid*). Further bombs fell near the barrage balloon positions south of Lloyd's Shoot and Henniker's Ditch (Newham War Damage Incident File).

Few air raids took place during the summer of 1941 as German resources were moved eastwards in preparation for the invasion of the Soviet Union, although the Boake Roberts Factory was hit yet again during the night of 27th /28th July (HO 198/46). No war damage was reported in the area between August 1941 and July 1942, though the Lee Conservancy Board reported that temporary repairs to a 40' (c.12m) length of walling near Old Ford Lock damaged the previous year had proved unsatisfactory, and that the towing path was in danger of collapse (LCB Minutes Vol. 65. No.2: 10, 06/02/42 RAIL 845/125). Because the cost of repair was estimated to be around £600, the board had to apply for Regulation 56A authorisation for work to proceed.

Though the Luftwaffe returned in 1943, most attacks tended to be nuisance raids carried out by small formations of aircraft. A brief episode of large-scale bombing took place during the 'mini-Blitz' of February and March 1944, when the London Docks were attacked once again. Few bombs were dropped on the Stratford area, though unexploded AA shells fell on the towing path at Hackney Marsh (Hackney Archives, HA/32), on the Redline Glico Works and in the Channelsea River near Abbey Lane (Newham War Damage Incident File).

Following the Allied invasion of Europe in June 1944, the Germans retaliated by launching the V1 Flying Bomb campaign against London and the south-east. Though the intensity of attacks declined in the autumn when Allied ground forces overran the early launch sites, significant damage was inflicted upon West Ham between July and September. During the night of 20th/21st July a V1 fell in soft ground at the north end of Gliksten's Timber Factory, approximately 70 yards east of the middle of the Lea. Steel-framed buildings at Gliksten's were destroyed, and damage was inflicted to the Sutton and Ashby Sack and Bag Works on the opposite bank of the Lea at Carpenters Road (HO 198/88). A second V1 fell nearby on the 27th August, detonating against the premises of the British Feeding Mills (i.e. the Wolsey Works), approximately 550' south of the Carpenter's Road Bridge (HO 198/93). Category 'A' damage was inflicted upon the brick-built structure, and blast damage occurred over a wider radius. It is likely that this V1 was responsible for the 'serious damage' suffered by the radial lock gate at the adjacent Carpenter's Road (Ward) Lock, reported by the Board towards the end of September (LCB Minutes Vol. 67 No. 10: 85, 29/09/44 RAIL 845/ 126). The gates were so badly damaged that they had to be returned to the Ipswich works of Ransome and Rapier, the firm that had originally designed and installed them ten years earlier (LCB Minutes Vol. 68 No. 1: 2, 05/01/45 RAIL 845/127; Joint Committee River Lee Flood Relief Act Minutes No. 41, 17/01/34). Emergency repairs to the fabric of the lock were carried out by the Board's own men, who

rebuilt the piers carrying the footbridge from which the gate operated and repaired the damaged fencing that had surrounded the lock (LCB Minutes Vol. 68 No. 1: 2, 05/01/45 RAIL 845/127). Though the lock-keeper's cottage on the east bank of the Lea was also seriously damaged by the blast, plans for repairs were postponed until September 1945 when the lock-keeper was due to return from service with the forces (LCB Minutes Vol. 68. No. 12: 91, 26/09/45 RAIL 845/127). It was anticipated that extensive work was required, including the rebuilding of an end wall, with costs estimated at approximately £500, for which authorisation was duly sought (*ibid*).

The final war damage incident in the vicinity occurred on 30th August, when a V1 fell on the west bank of the Lea, west of Waterden Road and approximately 300' (c.91m) south of the Eastway (HO 198/93). No category 'A' or 'B' damage was recorded, and no damage reports were submitted to the Conservancy Board.

Following the end of the war, permanent repairs that had been delayed by Regulation 56A authorisations continued throughout the second half of 1945. In addition to the rebuilding of demolished structures, minor repairs that had been postponed until the end of the conflict were resumed, such as the lighting at Old Ford Lock, which had been 'entirely destroyed' five years earlier (LCB Vol 68. No. 14: 120, 26/10/45 RAIL 845/127).

As the waterways began to resume operations under peacetime conditions, efforts were also made to rectify various emergency repairs that had been hastily carried out during the war years. As late as 1951 a length of river wall on the west bank of the City Mill River, which had been damaged during the war and subsequently demolished (Figure 39), was rebuilt to match the neighbouring stretch of 1930s wall with Larssen steel sheet piles surmounted by reinforced concrete capping (ACC/2423/X/129).

11 Development and function of the waterways: the back rivers from the post-war period onwards

11.1 Frank Pick's report for post-war development

The earliest plans for the post-war development of the Lea Navigation were devised by Frank Pick, and presented in his supplementary report on the Conservancy. In addition to his overall prescription for the revival of the inland waterways, Pick believed that the primary function of the Navigation would remain inextricably linked with the industry that had developed in the Stratford area over the preceding 150 years.

Given that aerial bombing had forced a number of firms to set up secondary production sites elsewhere, Pick thought it unlikely that those firms that had relocated to the northern stretches of the river would return after the end of the war, presenting an opportunity to concentrate industry '*at a point where efficient handling and servicing facilities for traffic could be economically provided*' (F. Pick, 'The Lee Conservancy': paragraphs 5 & 7, 31/01/41, MT 52/109).

Pick envisaged the creation of a 'considerable trading estate' on a 150-acre site the west bank of the Lea Navigation between Edmonton and Ponders End (*ibid*: paragraph 6). The new site would provide the first-class road and rail interchanges that Stratford so manifestly lacked, while the relocation of industry from the latter area would create an opportunity for improving the setting of those concerns that elected to remain (*ibid*: paragraph 6). Given that Pick believed that the future of the navigation remained dependent upon the transport of coal, he argued that greater priority needed to be given to the needs of the largest vessels that plied the waterways. The major physical hindrance to canal-going craft was the low clearance of road bridges over the waterways, a problem that had been identified and to some extent rectified in the Stratford area as early as 1936, but which had caused significant delays during wartime when the rivers were in flood (*ibid*: paragraph 9; Joint Committee River Lee Flood Relief Act Minutes No. 72, 14/10/36; LCB Minutes Vol. 66 No. 1, 05/02/43 RAIL 845/126).

Pick's recommendations for post-war development of the Conservancy shared a common perspective with those published by the Canal Association in 1945 (MT 52/150). The latter proposals were also predicated upon the assumption that future prosperity of the waterways would depend upon the carriage of heavy bulky loads (such as coal) for industry, for which undertakings needed to make better provision. Measures advocated by the Association included the rebuilding of old banks to allow power-driven vessels to operate efficiently, the reconstruction of low bridges, the electrification of lock gearing and the enlargement and duplication of locks (*ibid*).

While the proposals presented by Pick and the Canal Association were narrowly focused upon ensuring the survival of the inland waterways into peacetime, by 1944 it was apparent that any plans for the post-war development of the waterways had to take into account the new and ambitious plans for the future of the whole of Greater London that had recently been put before government ministers.

11.2 The Abercrombie plan

The most significant blueprint for the post-war future of the region was the Greater London Plan, prepared by Sir Patrick Abercrombie on behalf of the Minister of Town and Country Planning (HLG 71/144).

Abercrombie divided the Greater London area into four concentric rings: Inner Urban, Suburban, Green Belt and Outer Country and aimed to decentralise both industry and population from Inner London, under controlled conditions, to defined concentrations in the two innermost rings and to a network of New Towns that were to be built in the outermost zone. Abercrombie's vision of the role of inland waterways in the Greater London of the future was resolutely conventional: they would continue to serve industrial customers by carrying raw materials to, and finished products from canal-side factories, while established cargoes such as coal and building materials would be carried for commercial and domestic markets (Report by the Clerk of the Board and General Manager upon Sir Patrick Abercrombie's Greater London Plan 1944: 8, HLG 71/144). Abercrombie also repeated a number of suggestions made by Pick, including the reconstruction of Tottenham Lock and the establishment of new central collection and distribution points at key points on the network.

However, Abercrombie regarded the Lea Valley itself as an opportunity '*for a great piece of constructive, preservative and regenerative planning*' (*ibid*: 10). He proposed that large areas of open land in the Lea Valley, including the areas between Walthamstow and Enfield and the entire stretch between Hoddesdon and Hertford, should be 'welded into... great regional reservation[s]-[where] no open land, whatever its present use should be built on' (*ibid*: 11). Above 'Stratford Road' (presumably Stratford High Street) Abercrombie suggested that established open areas, such as the allotments and playing fields of the Hackney Marshes, should be preserved within their present boundaries, and that any future development should be restricted to those areas that were already industrialised.

11.3 The 1953 Transport Act, the Rusholme Report and their effects

After the 1953 Transport Act, which abolished the Executives and replaced them with boards of management under the British Transport Commission, the BTC decided on a private survey to make recommendations for the waterways. It was chaired by Lord Rusholme, a member of the Commission.

The results were reported in 1954 and published in 1955, listing many shortcomings in the system, particularly the lack of traffic due to changes from water to rail and road. The survey proposed that a nationalised system of waterways should be managed separately from the London docks, with a full-time general manager. It also suggested that the waterways should be considered in three groups: Group 1, 336 miles of already busy waterways which should be improved; Group 2, 994 miles of waterways which despite an uncertain future should be retained because of their value for commercial transport; and Group 3, 771 miles of waterways which seemed to have no commercial future and should be removed from the care of the British Transport Commission. Waterways in Group 2 could be transferred to Group 3 if their use dwindled.

The report was conditioned by the commercial value of canals, amenity hardly being considered. The groups were accepted by the British Transport, which sanctioned heavy expenditure on Group 1 waterways resulting in a number of improvements from 1956, notably on the Trent. However, the public were unhappy about the future of the canals in Group 3, many of which were valuable to pleasure cruising. Interest in the waterways and

pleasure cruising was growing, indicated by the foundation of the Association of Pleasure Craft Operators in 1953. An independent inquiry was appointed in response to this concern.

11.4 The Bowes Report

In 1956, the government appointed Mr H Leslie Bowes of the Pacific S.N. Co. and a committee of seven to undertake the independent inquiry into the future of the waterways and propose measures required to achieve maximum economic use of the system. The Bowes Committee Report was presented to Parliament in July 1958.

Having looked at both national and independent waterways they suggested 3 groups of waterways:

- The first, totalling 330 miles (531 km), they called Class A Waterways (of commercial use and to be developed);
- The second, totalling 1000 miles (1,609 km), they called Class B Waterways (worth keeping navigable but not of much commercial use);
- The third group, Class C waterways, totalled nearly 800 miles (1,287 km) and were considered to have insufficient commercial prospects to justify retention for navigation.

A and B together formed what the Committee called 'the prescribed navigable System', other users being recognised, including pleasure and angling. It was suggested that A and B should be put in good working order and maintained up to standard for not less than 25 years. Profits on A were to be used for their maintenance and improvement and the B system, with financial assistance, was to be brought up to a standard which would allow passage of laden craft of the largest dimensions designed for these waterways. On B waterways tolls were to be replaced by licences calculated on the capacity of the craft. The committee also recognised other users including anglers and pleasure cruisers.

Following the Bowes Report, some waterways were abandoned while others previously threatened by the Rusholme Report of 1955 were reprieved; the Norfolk Broads in particular were picked out as being essential to the economy of the area. The British Transport Commission agreed to maintain Class A Waterways to their current standards.

In 1959 an Inland Waterways Redevelopment Advisory Committee was set up to facilitate the redevelopment of Class C waterways. British Waterways encouraged pleasure cruising, especially following the Bowes Report. A hire fleet was set up with a new type of small cruiser designed by British Waterways, of which 28 were built, and 18 larger cruisers were made by the conversion of old narrow-boats. Trip boats were also built, with 11 in operation by 1960.

In 1960 converted carrying craft used for short cruises and 'entertainment' were operating on broad waterways in the London area and in the North Eastern Division. Yacht basins were established at Saint Pancras, London and Stourport and Worcester on the Severn, and a series of cruising booklets, the first of their kind, were published. Improvements to the system included the upgrading of many British Waterways properties, from cottages to operational equipment such as pumping stations. Other modernisations included the building of welfare facilities for boatmen at Hawkesbury, Wolverhampton and Bulls Bridge and the addition of sanitary facilities at repair yards. The busiest locks on Class A waterways were mechanised.

The Transport Act of 1962 reorganised the nationalised transport industries, abolishing the commissions including the British Transport Commission/British Waterways. In their place

independent boards were established; in the case of the waterways, the British Waterways Board. The Board had powers to develop, lease or sell its land, create pipelines, make its own equipment, acquire other undertakings and lend money. It was also given powers to borrow money.

11.5 The Transport Acts of 1962 and 1968

An amplification of the 1962 Act, the 1968 Transport Act gave even wider powers to the board, allowing it to manage hotels, provide ordinary road transport and provide amenity and facilities for recreational waterway activities. Of particular importance was the new three-group classification of the board's waterways into commercial, pleasure cruising (cruiseways) and the remainder.

The Minister of Transport had the power to transfer waterways from one group to another, and following the precedent of the 1888 Railway and Canal Traffic Act, closure of a waterway could be secured by Government order. The board was obliged to maintain its commercial waterways to suitable standard for freight-carrying craft, and the cruising waterways for pleasure craft. Duties of maintenance were enforceable by the courts.

The new act abolished any public or private right of navigation which might exist in any Act authorising any particular waterway, applicable to all waterways. Remainder waterways - the third category of waterways - were to be maintained as economically as possible, and the board was granted powers for their disposal, for example to local authorities. Local authorities were also empowered to subscribe towards the cost of improving the waterways for amenity use. The act also established the Inland Waterways Amenity Advisory Council, who were to advise on cruiseways and recreation.

The impact of the above on the rivers and canals of Stratford was unfortunately a negative one. During the 1960s and early 70s the area began to decline due to a combination of factors; partly the relocating of many heavy manufacturing industries outside of London during the Second World War, and partly the decreasing importance of London's waterways in comparison to the road transport network, which was a more flexible and efficient way for companies to move materials.

The waterways were, however, not wholly forgotten during this period; in 1965 Queen Mary College (University of London) applied for permission to build a Jason Type nuclear reactor on the west bank of the Pudding Mill River (commonly known as Lloyd's Shoot), gaining approval from the Nuclear Sites Consultative Committee on 17th February, 1960. Eventually the reactor was built in the College buildings on Mile End Road, as there was more readily available space, becoming 'critical' on the 10th of August 1964 and being dismantled in 1981. The documentation accompanying the licensing for the original Pudding Mill site states problems which faced both the Queen Mary College and existing businesses in the area.

'The proposed site is on one of the few large open spaces remaining in this part of London and the fact the many factories in the area have not already spread there, may be due to the presence of several rivers and canals which restrict access to the site to a light bridge. Whilst a new bridge to carry heavy traffic is now in existence, built specifically to serve the proposed site, the problem of restricted access still remains . . . These waterways, which are named the River Lea, Pudding Mill and City Mill River are all slow moving and highly contaminated by industrial effluent (POWE 74/301).'

By this date, the waterways has obviously deteriorated to a similar condition to their pre-1930s Flood Relief Act state, despite the works carried out in the 1930s and 1940s.

By the early 1970s there were plans to alleviate the Lloyd's Shoot area access problems. The plan was to construct a highway between Pudding Mill Lane and Marshgate Lane, which meant culverting the southern stretch of the Pudding Mill River. At this point, the question of ownership of the Pudding Mill River bed came to the fore. If the waterways were natural they belonged to the Crown, but if they were the result of artificial excavation they did not. A letter from the London Borough of Newham to the Crown Estate Commissioners outlines the confusion which surrounded the waterway and showed that competing interests were causing problems:

'The commissioners' claim that the river bed is vested in the crown is based on the contention that the river is tidal and some evidence to this effect was produced by you at the meeting in the form of an Ordnance Survey Map thought to be dated about 1930 whereon were shown Mean High Tide levels. You also submitted that the bed of a tidal river the flow of which was altered by artificial means remained vested in the Crown and that even if the works which are understood to have been carried out to the Pudding Mill River in the 1930s had significantly altered the tidal flow this was irrelevant so far as the question of legal ownership of the river bed was concerned.....the view of the council's officers, which appears to be supported by the Lee Conservancy Catchment Board's officers, is that the river is not at the present time a regular tidal watercourse, although it is possible that it was the effect of works which had resulted in this situation. On the other hand there did seem to be some reason (the title of river, for instance) for suggesting that the river was artificially constructed in the first place' (CRES 64/40).

The issue was resolved in 1973, in favour of the Newham Borough Council, and the construction of the Pudding Mill River culvert and highway took place in the same year.

The Pudding Mill River was not the only watercourse to be an source of contention for Newham Borough Council. The Channelsea had become severely silted (see Plates 9 and 10), and the council proposed to culvert the waterway. As with the Pudding Mill River, there was some dispute about whether the bed of the river was owned by the Crown. A letter of 1965, below, evidences the resolution of this dispute:

'Diversion of the Channelsea River

I refer to your letters of the 29th June and 14th July (1965), concerning the proposed diversion of the Channelsea River at High Meads Stratford, by British Railways (Eastern Region) and to confirm that that part of the existing River which is shown...on the enclosed plan forms part of the crown land estate under the management of this office.

2. The commissioners are prepared to grant a conveyance of the proprietary rights and interests of the crown in all the tidal land which will be affected by the present and future proposals to British Rail at a price to be negotiated on behalf of the commissioners by the district Valuer.

3. As the property forms part of the Crown Estate no title thereto shall be shown and no requisition or objection shall be made in respect thereof' (CRES 58/430).

The works of the 1960s and 1970s were aimed at removing waterways where they were an impediment to land access, rather than improving them. Without traffic, lacking in commercial importance, the waterways of the Lea valley simply slipped into decline, uncared for until the late 1980s when drives to ensure the green belt remained and London's green spaces were emphasised resulted in the tidying of towpaths and riverbanks, and the creation of the Greenway on top of the Northern Outfall Sewer.

12 Development and function of the recorded structures

12.1 Introduction: Henniker's and Potter's Ditches, and the Channelsea River (Figures 2 and 3)

The main watercourse in the area of Henniker's and Potter's Ditch area is the Channelsea River, an ancient waterway, known to have been in existence by at least the 8th century. The course and form of the river have been much altered by human intervention, including the construction of several ditches and sewers which drain into it. Among these are Potter's Ditch and Henniker's Ditch. Although ground raising in the area now means that the waterways run along the base of deep, artificial channels, some banking structures remain, including timber and stone structures.

The earliest historic maps, dating to the eighteenth century, depict the Channelsea River following a north–south course from the east end of Potter's Ditch. The Waterworks River lies at the west end of Potter's Ditch, also flowing north–south. However, this arrangement was altered during the 20th century: a length of the Channelsea River immediately south of the east end of Potter's Ditch was infilled, channelling all flow westwards along Potter's Ditch, then south into the Waterworks River. Further south, the Waterworks River connected to the remaining stretch of the Channelsea River, then infilled south of this point. This has created the current layout, in which a length of the original Channelsea River (henceforth the 'northern stretch') survives between Henniker's Ditch and Potter's Ditch.

Furthermore, the waterway immediately south of the western end of Potter's Ditch is a remnant of the Waterworks River, which now connects seamlessly with the surviving stretch of the Channelsea River further south.

12.2 OL-02007: Henniker's Ditch

Henniker's Ditch may represent a canalisation of streams belonging to the Leyton River, which may have flowed across the northern and western parts of PDZ6, or the manipulation of other natural watercourses that previously drained the valley side and flowed across the floodplain.

The name of Henniker's Ditch has its origins in the 18th century, as it is connected with a local landowner named John Henniker, who is depicted as having a residence to the south of the site adjacent to the Channelsea River in 18th century maps. By the 18th and 19th centuries it was certainly one of a series of drainage ditches running through the marsh immediately east of the Waterworks and Channelsea Rivers. During the 20th centuries many of these channels were culverted or backfilled and the river regime was also substantially altered, culminating in the present arrangement. Massive ground raising works were undertaken during the 1950s, -60s and -70s, with the Eastway Cycle Circuit being completed toward the end of this period.

Henniker's Ditch had recently (post 1970s) been culverted within a modern concrete embankment beneath the eastern end of the Eastway Cycle Circuit. The ditch extends to the west of this culvert and comprises high-sided natural banking. Following the ditch westwards, the southern bank is occasionally punctuated by in-feed drainage pipes. A wood and iron footbridge spans the ditch towards its western end, beneath which the banking has been strengthened with stone-shaped concrete revetting. At the western end of the ditch the flow is channelled into two large modern concrete pipes beneath the cycle

track embankment, after which it is directed southwards into the northern stretch of the original Channelsea River.

The flow from Henniker's Ditch emerges from beneath the cycleway concrete embankment via a protruding outflow pipe, approximately 1m above the waterline. South of this the waterway is defined by natural soil banking along its eastern edge and steeper embanked made ground along its western edge. Towards its southern end, the eastern bank of the waterway is revetted behind horizontal timber planking held in place by solid vertical timber posts spaced at regular intervals. Approximately 0.30m above the waterline the horizontal planking gives way to vertical plank shuttering that extends into the water. At the southern end of the waterway the flow turns west into Potter's Ditch.

Recent archaeological fieldwork by MoLAS-PCA has shown that the then-extant version of Henniker's, Ditch bore three distinct phases of cutting and re-cutting, beginning in the late 18th century (MoLAS-PCA 2007s). Earlier phases, which may have been present in this area, had been obliterated by the phase observed here. A second phase, dated to the second half of the 19th century, represents the earliest evidence of channels along the northern stretch of the original Channelsea River and Potters Ditch, suggesting that these have drifted eastwards and southwards respectively from their presumed original locations. The third phase represents the ditches as they were at the time of the fieldwork, and was dated to the deposition of substantial made ground during the 1950s to 70s.

The fieldwork also confirmed that evidence for Holocene channels might survive at the western end of Henniker's Ditch, suggesting that the watercourse followed the route of earlier topographic features (MoLAS-PCA 2007s).

12.3 OL-02007: Potter's Ditch

The wooden revetting described above continues along the southern bank of the eastern half of Potter's Ditch. It is damaged and degraded in places, in particular the eastern end of the ditch. The vertical timber posts are tied into the bank by plates and tie beams. How far these tie beams extend into the bank, and what they are fastened to, could not be determined due to the presence of Japanese Knotweed, which is prolific in this area. At its western end Potter's Ditch connects with the northern end of the remaining stretch of the original Waterworks River, which flows southwards into the southern Channelsea River.

12.4 The Channelsea River

In this area, this waterway is defined by steep, natural embankments. On the western side of the river a low-rising mudflat extends into the river course, often flooded at high tide. Along the southern half of its course the waterway bends, first to the west then to the east, resulting in an accumulation of debris forming a low bank on the western side that supports vegetation. Towards its southern end the waterway is crossed by a footbridge supported upon a modern iron grating with concrete surround, beyond which the riverbanks widen and the flow is less constrained. The banking at this point is formed of modern dumped deposits, creating soft landscaped banks down towards the river. The presence of the mudflats, and significant amounts of debris, precluded determination of whether any stone, timber or natural banking remained intact beneath or behind the made ground.

12.5 OL-05007: Old Ford Locks. OL-07307: Old Ford Lock Houses (Figures 2, 4 and 5)

The earliest drawn representation of Old Ford Locks and Lock Houses dates from an 1845 plan. In this incarnation the locks and lock houses were very simple; the double-chambered lock, toll both, stables and offices had yet to be built. At the location of the present-day lock houses the map shows four buildings, one of which is identified as a 'lock house'.

The lock is a single-chambered structure located on the eastern side of the Lea Navigation. Immediately west of the lock chamber is an island, labelled 'garden', and a ditch which runs the length of the Navigation until White Post Lane Bridge. It is probable that the ditch acted as a drain for surface water run-off and cesspits at the back of various properties (Figure 40).

The next plan of Old Ford Locks and Lock Houses appears on the 1869 OS map. By that date the 1850 Improvement Act had been put into action, and navigation between the Lea Navigation and the River Lea had been drastically improved. A brick-built double-chambered lock has replaced the simpler single lock of previous years. On the stretch above Old Ford Locks a new profile has been created by the widening and deepening of the channel, and the parallel cut of the Hackney Sewer on the west bank has been absorbed into the main channel. The buildings in evidence on the 1845 map are still present, with the addition of a smaller structure to the north. The land at the south of the building has been divided into three plots, the easternmost relating the East London waterworks waste channel and reservoir (Figure 41).

By 1896 the area around and including Old Ford had begun to change as more heavy industries moved to Stratford. The 1896 OS map shows that a towpath has been constructed on the east side of the Lea Navigation, either over or, more probably, infilling the previous East London Waterworks waste ditch, which had run down the entire length of the east bank. On the west side of the lock a new wharf has been constructed, in response to the increased traffic load (Figure 42).

An 1897 plan of Old Ford Locks shows the extent of the improvements brought about by the 1850 Act in more detail. The double chambers of the new lock, together with the north and south lock gates, allow for the increased passage of traffic at any one time. The new jigger mechanism had been introduced to the replacing the original push locks, and a pedestrian footbridge had been constructed (Figure 43).

A plan and elevation dating to 1908 show the creation of an internal bathroom (Figure 44). A plan drawn a year later shows that the house has progressed from a simple structure to three separate dwellings; two at the south for the lock keepers, and the third to the north, labelled as the collector's house. At the north of the property is the tollbooth, which in later years became redundant, eventually moving to the central island. At the south of the site, an un-annotated building which was in evidence on previous maps has been annotated for the first time as 'lock houses'. These would have brought in extra revenue to both the lock keeper and the Lea Conservancy Board, as the demand for a berth for a night from bargemen was constant (Figure 45).

By the 1920s and 30s the Lea Navigation and Lea River were in need of repair. Constant use over the years since their original construction in combination with little upkeep and pollution both industrial and sewage had created a situation where the rivers were in a deplorable state and the locks were in of repair. The 1930 River Lee Flood Relief Act allowed for improvement to the River Lea, Lea Navigation and associated back rivers. Two plans from the same period reveal that the lock gates and wooden dolphin protecting the central brick built island were to be replaced, although it was not until 1933 that the gates were actually changed (Figure 47).

The next major change at Old Ford Locks and Lock Houses is apparent on the 1948 OS map. The orientation of the lock houses has completely altered from the original 1800s north-south alignment to a new east-west alignment. The toll booth, which on previous maps had been at the northernmost extent of the property, has been moved further south, with a covered walkway joining it with the westernmost of the three houses. These changes were the result of a direct bomb hit on the locks on the 17th of October 1940, which destroyed the eastern and western lock chamber floors and gates, and severely damaged the central lock island and the original lock houses, collector's house and stables (see Plates 6 and 7). The lock was repaired before the houses, in order to keep the flow of much needed supplies moving in and out of London.

By 1945 the lock houses were still unoccupied, as an extract from the 1945 meeting minutes shows:

'Extensive damage was caused to this lock house which has not been in full occupation since the lock keeper went into service. He is expected back shortly and extensive repairs will be required' (RAIL 845/124, Vol. 68, No. 12: 91).

In the years following the Second War, the importance of the waterways declined as commercial traffic increasingly went via large container transport and lorry haulage companies. The Rusholme survey of Britain's waterways (see section 10) classified the River Lea and Navigation as Group 1 waterways, as they were in use and valuable to the timber and coal industries. The expenditure on upgrading Group 1 waterways which came out of the survey funded the mechanisation of the whole lock in 1958 (Figure 48).

The lock houses remained occupied by separate owners until the 1990s, when Channel 4 Television bought the property and used it for their 'Big Breakfast' show. The structural changes to the building to prepare it for its new use were considerable. The interior layout was altered, and the exterior of the building cement-rendered and painted. On the south-east side of the property a new two-storey extension was constructed with a roof-top garden. To the south-west another two-storey extension was added, which accommodated a stairwell and lift. In the area previously occupied by the tollbooth a shallow paddling pool was built, and to the east a cement-built Cyclorama added. By the late 1990s the show was no longer on air, and the house was used only for storage. An arson attack during this phase completely destroyed the roof, which was later replaced by the present, private owners.

12.6 OL-05407: Pudding Mill Lock (Figures 2 and 6)

Pudding Mill Lock is not a lock but a tidal gate, built in the 1922.

The OS map from 1916 shows the original Pudding Mill River junction, before the 1920s alterations which shifted the junction further south and saw the construction of the Pudding Mill tide gates (Figure 49 and Figure 19). A blueprint dating to 1922 shows the new tidal lock and associated metal anti-climb fence (Figure 50), and also shows Gliksten's timber yard on the west bank and the Charing Cross electricity station on the east.

The first date at which the gate is shown is 1948, on an OS map, where the east and west wing walls, a central island and an overhead footbridge with supporting piers are illustrated (Figure 51).

As use of the waterways declined, so naturally did most of their associated structures, including Pudding Mill Lock. By 1963 Pudding Mill Lock was no longer shown; likely, derelict (Figure 52). The decline of the waterways' importance in the area during the 1970s and 80s is represented by the map regression of this structure; by 1974 only the western side of the footbridge still remained. At present, the west bank of the River Lea is entirely

overgrown, effectively obscuring one half of the lock and any original fittings which may remain in that area (Figure 53).

12.7 OL-07407: Marshgate Lane Lock (Figures 2 and 7)

Marshgate Lane Lock was constructed in a single episode, dating to the 1930s building programme initiated by the 1930 Flood Relief Act. It was intended to alleviate the flooding which had hampered the area in previous years, most recently the 1928 flooding which had affected 1,200 homes (see paragraph 6.1). Under this scheme, the Waterworks River and Three Mills Wall River would be widened, and a drainage channel, new lock and associated lock house connecting the City Mill River with the newly widened waterways would be constructed.

Hollins Lock, as it was referred at the time, effectively created an artificial island, next to the 19th-century Pegshole Bridge, which is indicated by hatching on the 1916 OS map (Figure 54). Figures 55 –57 show how the new radial gates would operate, helping to control the problematic tidal flows that had previously hampered the area.

The OS map of 1948 shows little change in form from the lock's initial construction in 1932; the locks, footbridge and lock cottage are still in place. By this point the waterways were starting to slip into decline, eventually leading to the closure of Marshgate Lane Lock in the 1960s. The sluice channel connecting the City Mill River with the Waterworks and Three Mill Wall River became clogged and disused.

The area south-east of the lock which was originally a private transport depot was re-developed in the 21st century, triggering the partial restoration of the lock. However, the sluice was left unaltered (Figure 59).

12.8 OL-07207: Stone and brick riverbank wall (Figures 2 and 8)

The stone and brick built riverbank wall is first shown on the 1869 OS map, and was originally part of the stone-built wharf used by the Printing Ink Works and the Iceland Wharf Ammonia Works (Figure 59).

It is the only section of 19th-century river wall along the west bank of the River Lea to survive both the 1930s refurbishments and Second World War bomb damage.

The OS maps from 1916 to 1982 reveal that the same company owned the site until 2006, when it was redeveloped. The original river walling was retained (Figures 60- 62).

12.9 OL-03007: Carpenter's Lock (Figures 2 and 9)

Carpenter's Lock (originally Ward Lock) and Marshgate Lane Lock are the only two locks in London to possess a pair of double vertical radial gates, built more for flood defence than toll control.

The 1916 OS map shows that before construction, the lock site and surrounding land were uninhabited, making it an ideal location to build both a lock and lock cottage (Figure 63). The whole of the Back Rivers area had been prone to flooding, and by looking at the OS map it is immediately apparent that the Pudding Mill River itself was narrower than the upper reaches of the Lea. Therefore, any sudden increase in water level would have the potential to create flood hazards. Such was the case in 1928, when flooding of the general vicinity highlighted the need for more adequate protection and, in turn, helped to create the 1930s Flood Relief Act. The building scheme initiated by the Act, both improved and

changed the layout of the whole backwaters area; some waterways became wider and deeper, whilst other were infilled and the construction of various locks took place like.

During the Second World War a V1 bomb fell nearby on the 27th August, detonating against the premises of the British Feeding Mills (i.e. The Wolsey Works), approximately 550' (c.167m) south of the Carpenter's Road bridge (HO 198/93). It is likely that this was responsible for the 'serious damage' suffered by the radial lock gate at the adjacent Carpenter's Road (Ward) Lock, reported by the Board towards the end of September (LCB Minutes Vol. 67 No. 10: 85, 29/09/44 RAIL 845/ 126). The gates were badly damaged, with the result that they had to be returned to the Ipswich works of Ransome and Rapier, who had originally designed and installed them ten years earlier (LCB Minutes Vol. 68 No. 1: 2, 05/01/45 RAIL 845/127; Joint Committee River Lee Flood Relief Act Minutes No. 41, 17/01/34). Emergency repairs to the fabric of the lock were carried out by the Board's own men, who rebuilt the piers carrying the footbridge from which the gate operated and repaired the damaged fencing that had surrounded the lock (LCB Minutes Vol. 68 No. 1: 2, 05/01/45 RAIL 845/127). Though the lock-keeper's cottage on the east bank of the Lea was also seriously damaged by the blast, plans for repairs were postponed until September 1945 when the lock-keeper was due to return from service with the forces (LCB Minutes Vol. 68. No. 12: 91, 26/09/45 RAIL 845/127).

By 1948 the replaced lock and repaired lock house, surrounded by a small plot of land and a boundary wall, are visible on maps for the first time (Figure 64). It was in use until c.1960, for barges taking coal to the pumping engines at the waterworks which had originally given their name to the Waterworks River. However, as the waterways went into decline the lock was no longer as useful to commercial traffic, by 1970 the lock house had been demolished (Figure 65). Investment in the canal network during the 1980s saw some waterways and structures updated, one of which was Carpenter's Lock. Unfortunately this injection of life did not last, and the lock has since lapsed into a state of disrepair.

12.10 OL-03507: City Mill River Footbridge (Figures 2 and 10)

The 1869 OS map indicates the presence of a crossing spanning the junction of the City Mill River with the River Lea, although this does not appear in any later OS maps (Figure 66). By comparing the 1916 and 1948 OS maps it possible to suggest that the bridge was constructed during the intervening years (Figures 66 & 68).

Given the general alterations to the area associated with the 1930 Flood Relief Scheme, it is probable that this was also part of the scheme. However, no substantial documentary evidence has been found confirming this conclusion.

The large steel 'L' and 'T'-shaped flanges located between each open lattice or steel plate section were stamped 'GKB PT BRITISH I STEEL' and '[CO] NSETT' respectively. GKB stands for Guest Keen Baldwins Iron and Steel Company Ltd, which had works in Port Talbot and Cardiff. 'Consett' refers to the Consett Iron Company, founded in 1864 and merged into the Iron & Steel Corporation of Great Britain, created in 1949 when the major steel companies were nationalised. The companies that had been nationalised in 1949 were returned to private ownership by the Conservative government, when Sir Winston Churchill returned to power in 1951. In 1967 they were renationalised to form the British Steel Corporation.

12.11 OL-02707: The Pudding Mill River

The area between the Pudding Mill and City Mill rivers, to the south of Knobs Hill Road was densely industrial by the late 19th century. In contrast, the land between the Pudding

Mill River, the River Lea and the Northern Outfall Sewer remained relatively undeveloped, the only development by 1916 being the Metropolitan Water Board's Old Ford Pumping Station (demolished in the late 20th century) and a cottage.

Culverting of the southern section of the Pudding Mill River was undertaken, slowly reducing it in length from the south, from the late-1940s onwards. It assumed its current, shortened length in the period between the Ordnance Survey maps of 1960–74 and the present day. The current stretch of the Pudding Mill River ends just short of the Northern Outfall Sewer; its former course will lie buried and infilled beneath the southern half of PDZ3.

Both extant banks of Pudding Mill River date to after the 1930 act. The banks appear to have been constructed as one enterprise.

13 The waterways and built heritage

All archaeological analysis and recording during the investigation on site was done in accordance with the *Written Schemes of Investigation* (MoLAS-PCA, 2007), the *Museum of London Archaeological Site Manual* (1994) and MoLAS *health and safety policy* (2005).

The location of the structures was determined in outline on the modern Ordnance Survey plan. Details of the construction, development and function of the elements of the structures were noted. Notes on the form and fabric of the structures were taken, and the structures were photographically recorded. Manual scale drawings were undertaken where required.

The site records comprise a total of 3,189 digital colour photographic images, drawings, site notes, and notes on the documentary evidence. No objects or samples were collected. The site records will be deposited and indexed in due course in the Museum of London archaeological archive under the site codes OL-01207 (the waterways overall), OL-02007 (Henniker's/Potter's Ditches), OL-02707 (the Pudding Mill River survey), OL-03007 (Carpenter's Lock), OL-03507 (City Mill River Footbridge), OL-05007 (Old Ford Locks), OL-05407 (Pudding Mill Lock), OL-07207 (stone and brick river wall banks) OL-07307 (Old Ford Lock House) and OL-07407 (Marshgate Lane Lock).

These descriptions below should be read in conjunction with the selected photographs taken during 2007 (Plates 11-83).

13.1 The waterways

13.1.1 *Lea Navigation (Hackney Cut)*

The Lea Navigation runs roughly north-south within the site, entering the site beneath the East Cross Route at the north and joining the River Lea at its southern terminus. Within the site, it is crossed by four bridges:

- The first of these bridges is the Eastway road bridge, crossing the waterway as it enters the site at the north, carrying a slip road which gives access to the A12 East Cross Route (Plate 11).
- The second, lying halfway between the Eastway bridge and White Post Lane, is a pedestrian covered footbridge constructed from pre-moulded cement sections (Plate 12).
- The third, a short distance above White Post Lane, carries the East London line connecting west London to Stratford (Plate 13).
- The fourth and final bridge before the Navigation merges with the River Lea at Old Ford Locks is White Post Lane Bridge (Plate 14), carrying White Post Lane over the channel.

Most of the Lea Navigation banking is constructed of uncapped steel piles measuring approximately 12"x5" in profile. Each pile has a positive and a negative interlock, and are joined by alternating the orientation of the piles. They are secured to the bank by steel tie-rods and bolts in recessed panels (Plate 15). The area between the piles and the bank is infilled with poured cement.

Along the stretch of the eastern bank between White Post Lane Bridge and Old Ford Locks are three original tipping wharfs, of which two still have inset metal track rails (Plate 16). On the opposite bank is the entrance to the Hertford Union Canal.

The southern stretch of the east bank at Old Ford Locks is constructed of original ragstone blocks capped by cement block and granite coping.

13.1.2 River Lea

The River Lea runs roughly north-south within the site, with some meandering below Carpenter's Road. At the north, it skirts around the edge of PDZ15 and enters the site beneath Ruckholt Road. It exits the site at the south beneath Stratford High Street.

The Lea is crossed by ten bridges in the site:

- The first three, from the north, are in relatively close proximity to each other. The northernmost of the three is the road bridge for the A106 Ruckholt Road, followed by the road bridge for the A12 East Cross Route, then the road bridge for the Eastway slip road.
- The fourth bridge is a pedestrian footbridge, giving access from Waterden Road to the Manor Garden allotments on the east bank of the river (Plate 17).
- The fifth and sixth bridges are in close proximity to each other and are the railway bridge carrying the East London line, and Carpenter's Road bridge. At this point the river begins to enter into backwater area of the Lea Valley, where the Waterworks, City Mill and Pudding Mill all spring from the Lea. The Lea now begins a very marked meander, veering to the west until it reaches Old Ford Locks, then returning eastwards.
- The seventh bridge to cross the river is the pedestrian footbridge spanning the watercourse south-east of Old Ford Locks (Plate 18).
- The eighth is the Greenway bridge, carrying the Northern Outfall Sewer (Plate 19).
- The ninth and tenth bridges are in close proximity to one another, and both carry train lines.

13.1.2.1 The east bank

The southern stretch of the east bank, below Old Ford Locks, is constructed from steel coffered piling (see Plate 15). At the junction with the Waterworks River, banking is concrete over steel coffered piling. South of the former Great Eastern Railway bridge, there is a short section of stone riverbank wall with concrete capping. Protective timber dolphins were observed on both the north and south sides of the bridge's stanchions.

Old Ford Locks marks the point at which the Lea Navigation merges into the River Lea. It is at this point that the river meanders to the east with the east bank constructed from ragstone blocks, capped with concrete and granite blocks.

Between Old Ford Locks and Carpenter's Lock the river bank is constructed from poured and shuttered concrete with mooring hooks and drainage holes cut (Plate 21). Ragstone banking was observed at the junction with the City Mill River and brick banking immediately south of Northern Outfall Sewer.

13.1.2.2 The west bank

The southern stretch of the west bank, below Old Ford Locks, is constructed from steel coffered piling (see Plate 15). At the junction with the Waterworks River banking is concrete over steel coffered piling.

The riverbank between Old Ford Locks and Carpenter's Lock is heavily vegetated and obscured by modern wattling intended to encourage wildlife (Plate 20).

Along both east and west stretches of the Lea's banks are a number of mooring posts dating to the 1930s improvements. These were observed and drawn (Figures 69 and 70).

13.1.3 The Channelsea River

The Channelsea is split into three separate open stretches: two at northern extent of the Olympic site, running north-south either side of Potter's Ditch, and one short section which currently lies just outside the Olympic site and was not investigated. The Channelsea has earth banking, shallow on the east and steep to the west, creating a narrow channel (Plate 25). At the southern end of the westernmost section of the river, the banking on the east is constructed of horizontal timber planking reinforced by timber piles spaced at regular intervals. Approximately 0.30m above the waterline, the horizontal planking gives way to vertical planking, which extends below the water. Beyond its southern terminus the river is culverted, a result of works carried out in 1967 to enable construction of the Stratford Depot site at High Meads, as the area was then known (Figure 74).

Both the east and west banks of the Channelsea below Potter's Ditch become soft and wide with large amounts of modern dumping, and the flow is less constrained than that of the northern stretch between Henniker's and Potter's Ditches. The combination of debris and natural silting on the banks of the Channelsea meant that it was not possible to determine whether original stone/timber/natural banking was intact under or behind the current banks.

13.1.4 OL-02007: Henniker's Ditch

Henniker's Ditch, situated within the site of the former Lea Valley Park and Eastway Cycle Circuit, has been recently culverted to the east. The ditch extends from a concrete embankment at the east where the culvert emerges, running westwards between high-sided earth banking. Along this stretch, a number of drainage pipes open into the ditch from the south bank. A modern timber and iron bridge spans the ditch at its central point, and underneath this is a short section of modern concrete banking (Plate 22).

At the western terminus of the ditch, the water is channelled into two large modern concrete pipes that take the water underneath the cycle track to feed into the northern stretch of the Channelsea (Figures 71 and 72, Plate 23).

13.1.5 OL-02007: Potter's Ditch

Potter's Ditch is linked to Henniker's Ditch by a short north-south channel which is part of the course of the old Channelsea River. From the southern terminus of this section of waterway, Potter's Ditch extends westwards for a distance of approximately 67m before it joins the longer north-south course of the Channelsea, forming a dog-leg.

The north bank of the ditch is composed of steep embankments, covered by dense vegetation on the upper section. Heavy natural silting at the bottom, a result of regular tidal inundation, has formed mudflats extending into the watercourse.

Timber revetments, contemporary with those present on the eastern bank of the Channelsea to the west, line the south bank of Potter's Ditch. The timber piles are secured to the bank via a series of tie rods, bolts and plates. The full extent to which the rods extend into the bank and the type of anchors to which they are secured could not be determined due to the presence of Japanese knotweed (Plate 25). Further documentary investigation into the construction methods used on the waterways revealed that the rods are usually secured to concrete blocks (Figure 73).

13.1.6 City Mill River

The City Mill River is located between the Waterworks and Pudding Mill Rivers, the northern extent springing from the River Lea immediately south of Carpenter's Lock. Its southern extent is marked by Marshgate Lane Lock, at which point the City Mill becomes

the Bow Back River. In total the river is crossed by four bridges; at the north by the City Mill River Footbridge, which marks the junction with the River Lea (Plate 26); by Marshgate Lane road bridge, by the Great North-Eastern Railway bridge and finally by the Northern Outfall Sewer.

At the north, the west bank is constructed of shuttered and poured concrete sheets. Each sheet contains five pairs of square-cut drainage holes (Plate 27).

Immediately north of the former Great North-Eastern Railway Bridge is an area of timber pull-up piles which date to the construction period following the 1930 Flood Relief Act (Plate 28). Some fittings remain on this stretch of timber banking, including a possible sluice gate, one steel ladder, one iron ring, and an iron mooring staple. The area between the GNER bridge and the Northern Outfall Sewer contains a small mooring area, which at the time of recording was heavily obscured by vegetation, effectively hiding any original features or canal fittings from view (Plate 29).

At Marshgate Lane Lock, the sluice gate, which originally joined the City Mill with the Waterworks River, shows severe dereliction. The sluice gates are rusted and the sluice-way itself almost completely obscured heavy vegetation and silt build-up (Plate 30). The lock itself is also heavily overgrown, but shows signs of recent restoration (Plate 31). To the south of the lock on the east bank are an original cast iron access ladder and inset moulded access steps. These date to the original construction of this section of the waterway in the 1930s (Plate 32).

The southern end of the east bank is constructed of steel coffering with thick concrete capping. The rest of the east bank is mostly constructed from steep pre-cast concrete sheet piling covered with concrete caps. This type of banking is also present at the southern end of the river at the junction with the Bow Back River.

13.1.7 OL-2707: Pudding Mill River

Because the Pudding Mill is to be infilled in order to facilitate the development of the Olympic site, an electronic survey of its form and contours was undertaken. This can be seen in (Figure 75)

The Pudding Mill River is located south of the City Mill River, where it springs from the River Lea just south of Pudding Mill Lock. It extends only a relatively short distance to the south-east, beyond which it is culverted.

The river is spanned by four bridges, two towards the junction with the Lea at the north, a third towards the middle portion of the river and a fourth at the southern extent (Figure 2, and Plate 33). At the junction with the River Lea is an arched concrete footbridge, constructed from poured interlocking concrete sections, carrying the eastern towpath of the River Lea over the mouth of the Pudding Mill. Modern metal safety rails, painted black and white, have been added at a later date. The northern and southern towpath approaches to the bridge are surfaced by equally-spaced rows of granite risers, which do not appear to functionally relate to the bridge and may be earlier in date. South-east of the arched bridge is a modern bridge constructed of reinforced concrete. Safety rails painted in black and white have been attached to the north and south sides of the bridge (Plate 34). On the northern side of the bridge a low cofferdam had been constructed in an effort to control natural build up of silt and possible tidal surges caused by the confluence with the River Lea (Plate 35). The north-east and south-west banks between the first and second bridges are largely overgrown and obscured.

A large quantity of modern rubber tyres has been dumped both on the riverbanks and riverbed towards the northern extent, obscuring any historic features (Plate 36).

Immediately south of the obscured area of banking is the third bridge, which gives vehicle access from Marshgate Lane to the Queen Mary Engineering Institute. It is constructed of reinforced concrete, with footpaths on both sides and blue-painted handrails.

The visible banks are man-made and constructed from concrete piles with concrete capping reinforced by an extremely corroded RSJ running the length of both banks (Plate 37). Towards the southern end of the river is a modern timber bridge, which gives access to the Greenway (Plate 38). To the south of this bridge, on the east bank is a small rectangular-shaped platform constructed of poured concrete (Plate 39). No documentary evidence has been found to suggest what the original purpose of this structure was. North of this is another modern steel bridge which gives access to the Queen Mary College site from Marshgate Lane. (Figures 76- 79).

13.1.8 Waterworks River

The Waterworks River springs from the River Lea immediately north of Carpenter's Lock. Its southern terminus is marked by the crossing of Stratford High Street, at which point it becomes the Three Mills Wall River (Plate 40).

In total, the Waterworks is crossed by five bridges.

- At the north is the first, Marshgate Lane road bridge, which is just south of the junction with the River Lea.
- The second is a covered footbridge located just north of the third, which is the former Great North-Eastern Railway bridge.
- The fourth bridge carries the Northern Outfall Sewer and is constructed of concrete, encasing the two main sewage pipes.
- The fifth and final bridge carries Stratford High Street and is a modern construction, a combination of metal and concrete elements. The north-western side of the bridge marks the south-eastern edge of the Olympic site.

Both the east and west banks along this stretch are constructed from steel sheet piling capped by battered and poured concrete. At regular intervals along both banks, original mooring hooks, timber pull-up piles and iron fencing remain in situ. Both banks contain square drainage holes at regular intervals along the entire length of the river.

The towpath lies on the north-eastern bank of the river and is constructed of concrete slabs, which at various points along the northern stretch give access to the drainage system via hatches. Access to all points along the banks of the river was prevented by the presence of industrial buildings.

13.1.9 Bow Back River

The Bow Back River is located at the south-eastern end of the Olympic site. Marshgate Lane Lock marks its northern terminus, beyond which the Bow Back becomes the City Mill River.

It is spanned by two bridges; Marshgate Lane road bridge towards the east and Blaker Road bridge to the west.

The banks of the north-eastern stretch of the Bow Back are predominately constructed of ragstone blocks, while the south-western stretch towards the entrance of the River Lea is constructed of steel-capped piles.

During the 1930s this section of waterway saw extensive alterations, which resulted from the 1930s Flood Relief Act. This Act created the watercourse and banking which is visible today (see Plate 32).

13.2 Built heritage

13.2.1 OL-07307: *Old Ford Lock Houses*

Old Ford Lock Houses are located within a plot of land on the east bank of the River Lea, immediately to the north-east of Old Ford Locks. The plot lies on a tip of land defined to the south-east and south-west by the River Lea and the Lea Navigation respectively. Bow Industrial Estate encloses the site to the north.

The houses are semi-detached and two-storey, with a tiled roof. Rectangular in plan, they possess an east-west orientated single-ridged hipped roof. Three brick chimneystacks rise from the roof (Plate 41). Three original terracotta finials survive, and have been stored in the south garden along with some chimneypots (Plate 42).

Extensive remodelling by Channel 4 Productions for the 'Big Breakfast' show in the early 1990s, an arson attack and alterations by private owners have meant that most of the door and window casements are modern replacements. The most recent and obvious alteration is the cement-rendered façade, 0.025m thick, which imitates a red-brick Flemish bond facing on the exterior of the building. The attic space has been converted, with skylights set into the roof on the north side and modern dormers on the south side.

The principal elevation is to the south. Access is gained via a door in the centre of the ground floor west elevation. The east side of the building has two back doors, one of which is no longer in use. The functional door gives access to the new extension on the north-east side of the original building.

In plan the area covered by the building measures roughly 13m from north to south and 19m from east to west. All external elevations together with the form and fabric of the building will be described.

13.2.1.1 *South elevation (see Plate 41)*

The brickwork is entirely faced in cement rendering painted to resemble red brick in Flemish bond (see above), but for the first three brick courses up from ground level. These are visible but have been painted black, hiding the original colour and fabric of the brickwork and mortar.

The original door and window arrangement is still evident on the west side of the elevation, comprising a modern metal casement window and doorframe at ground floor and two modern metal casement windows at first floor. A later dormer window has been inserted in the roof.

At the centre of the elevation is a modern double patio doorway with single sidelights on both sides. The patio doors lead from the house onto a raised, paved area, with a dwarf wall of blue/purple engineering bricks on the east and west sides. Two steps lead down to the main portion of the south garden. The first floor has a modern triple metal casement window and a dormer window in the roof.

At the eastern end, access to the house is via a metal-framed double patio door on the ground floor, which leads from the house into a small fenced-off portion of garden. At first floor are two windows, one an original window opening with a modern metal casement, the other a casemented panel window, which extends upwards from ground to roof level. All windows and doorsills are constructed from slate tile.

Three original chimneystacks are visible on the south elevation; one is centrally located within the roof, and the other two are set into the east and west mass walls.

13.2.1.2 North elevation

From the eastern end of the north elevation a modern single-storey extension projects to the north, containing a workshop and corridor, accessed via a door in its north elevation. At the east of the modern extension is a steel staircase giving access to its roof. The roof of the extension has been paved creating an outdoor space. A modern metal-framed double French door at the first floor level of the eastern end of the cottage gives access to the roof garden from the main house (Plate 43).

At the west end of the north elevation, a further extension, housing an internal stairwell and a modern chimney, extends to the full height of the house. In its north elevation is a casemented panel window extending from approximately ground floor ceiling height to first floor ceiling level.

The original part of the building has a series of access points on the ground floor: one modern double patio door with single sidelights on the east and west sides in the centre of the elevation; one modern double patio door to the east and one original single doorway to the west. At first floor there is a casemented panel window extending the full height of the storey at the eastern extent, with a centrally-placed triple metal casement window and a double metal casement window at the western extent. The roof contains three modern skylights, two of which are located in the central portion of the roof, the third on the eastern side.

13.2.1.3 East elevation

There is single-storey modern extension at the northern extent of this elevation, which is described as part of the north elevation. The original part of the building has a centrally-placed single door with metal frame containing fixed glass panes at ground floor, but this is no longer in use. Immediately north of this is a double metal casement window. The access point in current use is in the north end of the modern extension and is a single, reinforced timber and steel doorway.

At first floor level is a double metal casement window which is smaller than the ground floor window, indicating that the opening is probably original but the casement is modern.

13.2.1.4 West elevation

The original part of the building has a centrally-placed metal-framed doorway on the ground floor, which gives access to the building's interior.

The first floor has a casemented panel window extending upwards from approximately ground floor ceiling height to first floor ceiling level (Plate 44).

13.2.1.5 Gardens of Old Ford Lock Houses

The area surrounding the main building has been divided into north and south gardens, with the entire western side bounded by a white picket fence. The north garden has a modern layout designed for the Channel 4's 'Big Breakfast' show.

The south garden retains hints of the original layout. The areas to the east and west of the house are partitioned off with white picket fencing, and the central portion of the garden has no fencing but low hedges instead.

The north garden has a raised gravel patio immediately in front of the houses, surrounded by a dwarf wall which leads to an Astro turf lawn with a centrally placed circular swimming pool 4ft deep. To the north-west of this is a tall, curved breezeblock wall measuring 3.65m in height, the south face of which has been painted to show a sunrise. The north face is

supported by brick buttresses. Behind the wall to the north is a series of sheds and temporary structures used to house props and other filming materials.

On the west side of the building is a greenhouse and a footpath which gives access to the south garden. In the south-west corner is a curved cement-rendered breezeblock wall with a painted red-brick façade in a header bond pattern. This conceals the septic tank, garden waste heap and machinery. The east boundary wall is early 20th-century in date with a poured concrete foundation and buttresses, and is constructed from smooth brown brick and yellow/grey mortar set in an English bond pattern. The top of the brick wall is stepped and is obscured by ivy. Access into the property and gardens is via a double gate on the western boundary opening onto the Hackney Cut and Old Ford Locks towpaths (Plate 45).

13.2.1.6 Stable block of Old Ford Lock Houses

In the south-west corner of the garden is a small rectangular structure which is outside the modern garden boundary, but which originally functioned as the stable block associated with the lock houses. The building is a single-storey structure with a poured concrete foundation, constructed using yellow stock bricks and grey mortar set in English bond pattern, the first two brick courses of which have been covered by cement rendering. The roof is pitched and has been covered with terracotta ridge tiles. The southern half has been converted into a public toilet block, and the northern half is used for storage. To the east of the stable block is an area of granite sets, which may be original landscaping associated with the stables (Plate 46).

13.2.1.6.1 NORTH ELEVATION

This elevation contains a single gable-end window with a concrete lintel and ceramic tile sill, the exterior of which is shuttered with horizontal wooden slats. The roof possesses bargeboards.

13.2.1.6.2 EAST ELEVATION

This elevation contains two original high-set windows to the north, now boarded, with ceramic tile sills. At the south end are four later modern timber-framed windows containing safety glass within a barrel frame. All have internal vertical safety bars and concrete lintels.

13.2.1.6.3 SOUTH ELEVATION

This elevation contains one original gable-end window, with a concrete lintel and ceramic tile sill. It is shuttered externally with horizontally set wooden slats. There is a further, modern inserted window at the west, which has a wooden frame and sill, concrete lintel and two opaque fixed safety glass panes. To the east of this window are three vertical scars extending up from the building's concrete foundation to approximately 2.06m in height, indicating that a single-storey addition, 2.70m wide, was once keyed into the main stable block at this point. The poured concrete flooring of this structure is still in place. The central scar is a partition wall, approximately 0.11m in thickness. The external face of the stable block wall between the partition and outer scars still bears evidence of paintwork, with the top half painted cream and the bottom half painted black. All three vertical scars rise to one timber lintel.

The rake is visible on this elevation, revealing the underlying asphalt waterproofing used in the roof's construction.

13.2.1.6.4 WEST ELEVATION

The west elevation has two access points and a single modern window. To the north is a doorway, which gives access to the storage part of the building. It has a modern steel-framed double doorframe with steel door and a concrete lintel. To the south is a single steel doorframe and door, which gives access to a modern public toilet. Immediately north of the

doorway is a single steel framed casement fixed pane window with an overhead awning window and tiled sill, the interior of which has vertical bars. Both share a single concrete lintel. The brickwork surrounding the window and parts of the doorway reveal has been replaced in order to house these modern additions.

13.2.2 OL-05007: Old Ford Locks

Old Ford Locks straddle the Lea Navigation (Hackney Cut) immediately north of its junction with the River Lea, immediately west of Old Ford Lock Houses.

The locks are a combination of a lock and weir system (Figures 1 and 5). The lock itself is formed of a central dolphin island, with two double steel swing mitre lock gates. The toll/control booth stands on the central part of the island. The northern and southern extents of the lock beyond the lock gates are known as pounds. The position of the lock is significant, as it marks the junction between the 'new' Lea Navigation and the 'old' River Lea (Figure 80 and Plate 47).

13.2.2.1 Upper pound, north of locks

On the eastern bank, immediately north of the locks, is a timber structure, constructed of five vertical posts with a pair of horizontal beams. The posts have barrel caps with steel covers, below which are steel collars. The 3rd and 5th posts are constructed from concrete with wooden casing, creating a sympathetic appearance. Between the two northern posts is an earlier post worn to a stump. The horizontal beams are attached to the vertical posts via coach bolts on the towpath side. The timber piles are linked together by rounded buffer plates on the canal side (Plate 48).

On the west side of the north pound is a timber structure extending approximately 5m out from the bank, consisting of three vertical posts with barrel tops and iron collars, and two horizontal beams with iron collars. This structure is most probably a weir, which is first located on a plan dated to 1897 (Figure 44). The by-wash is situated to the west of this structure.

13.2.2.2 Central dolphin island

The northern and southern tips of the island are constructed from a wooden framework consisting of beams attached to vertical piles and are V-shaped in plan. The northern tip is covered by timber planking and a galvanized steel grille. There is a half-domed steel cage structure at the tip, composed of three horizontal bands and five vertical bands painted white, with a solid metal back-plate painted black. The cage is used to house two navigation lamps, one red for port at the west, and one green for starboard at the east, intended to aid navigation into the locks. The cage sits on a metal base plate and has a rubber tyre attached to the front of it, which acts as a buffer protecting both the tip of the island and the sides of the barges (Plate 49).

The southern tip is set at a lower level than the northern tip, and is accessed by a modern steel ladder attached to the footbridge which spans the lock. It carries a single mooring bollard.

The east and west sides of the island also form the inner walls of the east and west chambers and are constructed from granite blocks, with the outer edges painted white. Within the island, the area between the east and west granite sides is surfaced with red brick laid in a herring-bone pattern, with a border composed of red bricks laid on bed. There is a 'T' shaped mooring bollard, immediately south of the island's north tip, which is set in a north-south alignment. A raised concrete casing and inspection covers for the machinery which operate the lock gates and the cloughs is situated at each end of the island (Plate 50).

There is a small rectangular hut situated in the central part of the island, which is constructed of yellow stock brick set onto a concrete base, with steel windows and doorframe and a flat concrete roof. Along the front and rear of the cabin are safety barriers.

Some of the lock's operational controls are within this hut. At the southern end, by the footbridge, there are electric controls set into a concrete lectern (Plate 51).

13.2.2.3 East and west lock chambers

Both chambers appear to be constructed mainly from yellow stock brick, with some later repairs using blue engineering brick. These brick walls are capped with large granite blocks which measure approximately 1.20m x 1.05m x 0.67m. The waterline at the time of recording measured 2.90m from the top of the granite coping, on the south side of the lock (Plate 52).

The sills within the chambers are constructed from granite blocks. The upper parts are painted white, with the word 'CILL' and a downward pointed arrow painted in black.

There are two styles of hinges for the gates. The earlier style has two arms, which are bolted into the top of the granite sill. The later type has a metal plate (Plate 53).

13.2.2.4 East chamber

The east lock chamber is used regularly. The gates have '1993' inscribed on them, and can be assumed to be modern. Original breast posts and heel post timbers have been re-used on the outer edge of each gate, along with the pivot hinges and the arm for opening and closing the gates. The rest of each gate is made of steel with 4 horizontal bars above water level. The north side of each gate is clad with a single steel sheet.

On the east, brick-built wall of the east chamber there is an original square recess containing circular metal rungs (Plates 54 & 55). Above the brickwork is a rectangular recess, which houses the lock clough. Above this is the piston housing, set into poured concrete 1.27m thick which also encases the machinery for the lock. Along the outer edge of each recess is a curved vertical steel plate to protect the brickwork of lock, commonly known as a rubbing iron.

There are four rectangular metal inserts with two small mooring-pins on each side of the lock chambers.

In the west wall of the east chamber is a semi-circular recess running down the side of the lock wall. A modern ladder has been inserted with four rungs at the top of the recess. To the south of this ladder is a rectangular recess with a metal mooring pin.

At each end of the locks are a pair of stop grooves to house stop planks, which can be slotted in to prevent water entering and enable work on the lock structures. These are set outside the chambers (Plate 56).

13.2.2.5 West chamber

The west chamber is no longer in use. The north gates are permanently open and the south gates permanently closed. The water level on the 19th Oct 2007 was 0.26m below the granite edge.

On the west side of the lock is a timber buffer constructed of a series of three vertical wooden piles and horizontal beams, which is situated approximately 5m from the bank. The piles have barrel tops with iron collars, and the two horizontal beams also have iron collars. This helps to form a channel into the west chamber whilst also protecting the weir to the west.

The lock gates are formed of an oak beam frame. Three horizontal beams are visible above the waterline on the south face of the south gate. The inner, north face of this gate consists of a series of vertical close-fitting thick planks.

13.2.2.6 The lock machinery

The machinery is housed within a poured concrete structure, which is located on the central lock island. The mechanism for the locks is powered by electric pumps, pumping water under pressure into a piston cylinder to open and close the locks and clough-gates in the side of the locks.

The machinery for the lock gates are horizontal pistons with steel inspection covers above. The gates are opened and closed by an arm at the top. The machinery for the clough-gates is set vertically within a steel square column on the edge of the chambers, directly over the cloughs (see Plate 51).

13.2.2.7 Lower pound, south of locks

Beyond the lock, the granite blocks which form the east and west chamber sills within the lock itself change to yellow stock brick set in an English bond pattern above courses of blue engineering bricks (Plate 58).

13.2.3 OL-05407: *Pudding Mill Lock*

Pudding Mill Lock (in fact a tide gate rather than a lock proper) is located across the channel of the River Lea north of Old Ford Locks and the confluence of the Lea with the Pudding Mill River (Figures 1 and 6).

It is constructed of stone, blue brick and steel. The three structural elements of the lock comprise two brick-built chambers, each with a brick-built pier, situated on the northern end of the east and west banks respectively; and a single central lock island, which also has a centrally located brick-built pier (Figures 81 and 82, Plate 59).

For the lock's construction, the east bank of the River Lea was extended with an artificial promontory known as a wing wall. This is constructed of reinforced poured shuttered concrete, angled towards the bank (see Plate 59).

Beyond the promontory is a lower platform, which originally housed the eastern tide gates. The platform is constructed from poured concrete slabs capping the original ragstone coping blocks which extend approximately 1.40m below the waterline. Later root action on the central portion of the platform has created large cracks and shifted the poured concrete slabs, creating a slope which angles towards the eastern bank (Plate 60). The south end of the eastern lock platform is damaged and has had protective timber posts attached, which extend towards the mouth of the Pudding Mill River. The same damage has caused a metal mooring post to dislodge (Plate 61).

Below the poured concrete of the promontory and platform the original ragstone walling is still evident. A brick retaining wall topped by iron railings and an iron gate, which is painted black, are the remnants of the original 1920s anti-climb railings (Plate 62, Figure 51). The iron gate leads directly to concrete steps, giving access from the towpath to the wing wall promontory.

At each end of the lock is a set of square stop-gate slots with the remains of the three-sided iron sleeves. The lock gate hinge plate remains, and is of iron set on top of the sill. A mooring bollard also remains in place. At the north-east end timber piles emerge from behind the retaining wall and continue to the bank of the River Lea (Plate 63).

13.2.4 OL-07407: *Marshgate Lane Lock*

Marshgate Lane Lock (or City Mill Lock) is situated at the between the Bow Back River and the City Mill River leading into the Waterworks River (Figures 1 and 7 and Figure 83, Plate 64).

The banks leading into the lock are all formed of poured concrete over concrete shuttering. The lock itself comprises a single chamber with cofferdamming at either end. There are three sets of lock gates with a footbridge over. The sides of the chamber are formed of poured concrete, capped with large sandstone blocks.

The north side of the chamber is also the edge of the island on which the lock-keeper's cottage stands, surrounded by the Bow Back River, City Mill and Waterworks River (Plate 65). Built in 1935 in the mock-Georgian style, it has a pedimented and pilaster timber door surround. The window openings are also mock-Georgian with modern white plastic double-glazed frames. It has a pan-tile hipped roof with two chimneystacks. The upper (first floor) storey is rendered in cement and the building is painted bright blue. The garden shows signs of being in the process of being refurbished. A mono-block patio has been laid on the east and west gardens of the house (see Plate 65).

The vertical timber buffering on the west tip of the island and timber guard posts on the opposite bank to the entrance. At each end of the lock there is a depth gauge. The east and west lock gates are no longer in operation (Plate 66).

On each side of the chamber there are two iron mooring hooks clad in timber, recessed into the walls. There is also an iron access ladder recessed into the wall.

At the eastern, 'out' end of the chamber are two pairs of lock gates, and at the entrance at the west, a single pair. These are very modern and are made of steel. The ends of each gate have a large vertical timber beam capped in galvanised steel. The 'out' gate at the eastern end of the chamber has no sluice paddles, where the other two pairs of gates have one on each gate. The operating machinery has been removed. At the eastern entrance there are a series of guard posts continuing round onto the Waterworks River. An access ramp coming off Blaker Road onto the lock system of the island, has a series of granite riser sets to aid horses walking up the slope from the lock.

13.2.5 OL-07207: Stone and Brick Riverbank Wall

The riverbank wall in question is situated on the west bank of the River Lea and begins immediately south of the Greenway Bridge, extending southwards for approx. 150 metres. Starting from the northernmost end, the first part of the wall is constructed of ragstone ashlar blocks which in turn are capped by early 20th-century poured concrete (Figures 1 and 8). Only four courses were visible above the waterline at the time of recording. At the northernmost extent of the ragstone walling, a disused outflow pipe is visible, which may contain a culverted stream flowing into the River Lea (Plate 67).

South of this, the riverbank is protected by interlocking Larsen steel coffering, followed by four-and-a-half courses of ragstone block ashlar above, capped with thick early 20th-century poured concrete. The coffering may suggest an access point or slipway onto the river (Plate 68). Within the concrete there are two small outflow pipes with hinged metal caps to stop the river water from entering. On the river bend, the banking changes from poured concrete to irregular courses of roughly-hewn stone capped with large ragstone blocks. Further along, the capping changes to concrete (Plate 69).

The red-brick boundary wall of the Autumn Street works signals a change in the river wall height. Due to dense vegetation most of the wall's southern extent was obscured and further investigation was not possible. That part of the wall which was visible and above the waterline is constructed of ten courses of red brick set in Flemish bond pattern, followed by a single course of sandstone blocks and finally capped with a course of ragstone ashlar blocks. Above this is an early 20th-century flood protection wall which has been incorporated into the foundations of the structure above, which is a reinforced concrete frame with brick infill set in an English bond pattern, with a gable end overlooking the river (Plate 70).

13.2.6 OL-03007: Carpenter's Lock

Carpenter's Lock is situated on the River Lea between the mouths of the City Mill and the Waterworks Rivers. To the east of the lock is a modern scrap yard, and to the west of it is Carpenter's Business Park (Figures 1, 9, and 84-86, Plates 71 and 72).

The gates and associated structures will be described separately and referred to as 'north' and 'south'.

13.2.6.1 South lock gate

The southern lock consists of concrete embankments to the east and west, with red brick piers on both sides. The piers are each set onto a concrete chamfered plinth and have a single brick course set in a rowlock bond pattern at the top and base (Plate 73). Access stairwells are set into both piers on the north elevations, in turn acting as supports for an overhead concrete walkway

Along each overhead walkway is machinery relating to the lock pulley cables, which run down through access holes cut into the concrete and into machinery chamber below (Plate 74). The east pier also has an access ramp on the south elevation, which is constructed of poured concrete with evenly-spaced single rows of inset granite risers (Plate 75). These are similar in form to the tipping wharfs on the Lea Navigation's eastern towpath north of Old Ford Locks (see Plate 16).

13.2.6.2 Machine room of south lock gate

The gate mechanisms are housed in a machine room underneath the eastern access stairwell. The original mechanisms have been superseded by a modern pulley system (Plate 76). A single doorway gives access into the room, the lintel and threshold of which are constructed of red brick. The room is divided by a east-west brick-built dwarf wall. The machinery is housed in the southern half of the room and consists of a pulley and cable system. The cables feed upwards through an access point cut in the concrete. Cut into the concrete floor directly below is a rectangular pit in which a weighted metal pulley reel ballasts the mechanism. The south and west internal walls have a brick plinth which extend outwards by one brick's width and is approximately five courses up from floor level.

13.2.6.3 North lock gate

The northern lock consists of concrete embankments to the east and west, with red brick piers on both sides. The piers are each set on to a concrete chamfered plinth and have a single brick course set in a rowlock bond pattern at the top and base. Access stairwells are set into both piers, on the north elevations, acting as supports for an overhead concrete walkway. Along each overhead walkway is machinery relating to the lock pulley cables, which run down through access holes cut into concrete and into a machine room below. Access into the room was prohibited due to fallen machinery (Plate 78).

13.2.6.4 Around the lock

To the south of the lock is a structure constructed by Thames Water, associated with sewage or water passage. The structure consists of two concrete rectangular structures, one on each bank, with two metal pipes running between them spanning the width of the River Lea. Access into the east building is via a single doorway on its east elevation.

One mooring post sits on the corner closest to the canal and the lock; the north-east corner, opposite is obscured by vegetation. The only other remaining fitting is an iron-runged access ladder on the north bank of the canal (Plate 77).

13.2.7 OL-03507: City Mill River Footbridge

The City Mill River Footbridge is situated over the mouth of the City Mill River where it meets the River Lea, south of Carpenter's Lock (Figures 1 and 10). It allows the eastern towpath of the River Lea to continue northwards towards Carpenter's Lock and the Waterworks River. It is associated with the 1930s flood relief scheme and has seen little alteration since its original construction (Figures 87 and 88, see Plate 26).

The City Mill River Footbridge is a trussed arch bridge constructed from riveted steel components. A curved central section, with riveted open lattice plate sides stiffened radially with 'L' and 'T'-shaped flanges, is joined overhead with steel plates. The lattice sides are composed of individual steel bars, separated by shims at the points at which they are riveted together (Figure 88 and Plates 79 and 80). Shims are thin pieces of steel, which act as spacers often where components are subject to wear. This is supported by straight-end sections anchored into the concrete walls of the canalised river, with steel plate sides gradually lowering to the ends and stiffened vertically and horizontally with steel plate members. The northern and southern sides of the bridge are anchored together by steel plates, and the space between filled with concrete cast in situ (Plate 81).

Tubular steel handrails bolted to the horizontal steel plates at the western and eastern ends compensate for the lower height; these handrails extend further along the footpath at the eastern and western ends (Plate 82). The footpath carried by the bridge is composed of concrete, with bands of six granite sets at intervals of approximately 50cm. Open salt-glazed earthenware drain pipes are incorporated into the footpath surface on the southern and northern sides (Plate 83).

14 Discussion

14.1 OL-01207: The waterways overall

The extant waterways themselves fall into six distinct episodes of construction and alteration:

- The first phase dates to the 1700s, with the creation of millstreams in the marshland area, creating the braided channels and small islands typical to the valley.
- The second phase dates from the mid- to late 1800s, a programme of construction spearheaded by the newly created Lee Conservancy Board.
- Phase three took place in the 1930s, with improvement of the back rivers. Watercourses were widened, dredged and the banks improved, action which was sorely needed after years of complaints from residents and landlords alike.
- World War II marks the fourth phase, which mainly consisted of upkeep, and repair to the rivers and structures after bomb damage.
- Phase five dates to the 1950s, when some improvements which were originally envisaged during the 1930s were finally carried out.
- Phase six comprised the infilling and/or culverting of some watercourses during the 1960s and 1970s; by this point the waterways were in a gradual decline, partially as a result of 1950s schemes which proposed the abandonment of the canals for commercial use in favour of recreational use.

A final, seventh phase of alteration to the waterways does not relate to construction, but rather a long period of abandonment and lack of maintenance from the 1980s to the present day.

14.2 OL-02007 Henniker's and Potter's Ditches

Henniker's Ditch had seen recent culverting. Extending from a concrete embankment at the east where the culvert emerges, then westwards between earth banking. Drainage pipes open into the ditch from the south bank and a modern timber and iron bridge spans the ditch at its central point, underneath which was modern concrete banking. The western tend of the ditch drains into concrete pipes that feed into the Channelsea. The surviving form of the ditch dated to the deposition of substantial made ground during the 1950s to 70s. No earlier phases or related structures were recorded.

Potter's Ditch, linked to Henniker's Ditch by a north-south channel which then turned west was similarly bounded by steep embankments. Although some timber revetments, contemporary with those present on the eastern bank of the Channelsea to the west, line its south bank, the surviving form of the ditch dated to the deposition of substantial made ground during the 1950s to 70s. Again, no earlier phases or related structures were recorded.

14.3 OL-02707: Pudding Mill River

An electronic survey of the form and contours of The Pudding Mill River was undertaken. The banks were modern, man-made and constructed from concrete piles with concrete capping reinforced by an extremely corroded RSJ running the length of both banks. Despite

the presence of the remains of towpaths, the river was truncated, with its southern extent culverted. Rubber tyres has been dumped both on the riverbanks and riverbed in the open, northern stretch. The Pudding Mill River had not been maintained, was not able to serve any function and was generally disregarded.

14.4 OL-07307: Old Ford Lock Houses

The lock houses at Old Ford illustrate the important commercial role formerly played by the junction of River Lea and the Lea Navigation. The lock workers who lived there marshalled the commercial traffic through the locks, collecting tolls and ensuring that the commercial traffic of a rapidly expanding London could flow in and out of its commercial and manufacturing centres easily.

From the 1970s onwards, this area changed. The infrastructure focus shifted to the newer and faster road and rail networks, meaning most canals and rivers declined in importance. Once an important part of industry in Stratford, most of the River Lea and Lea Navigation became an areas for recreation or neglect, their past forgotten and outgrown.

The lock houses have survived the area's changing fortunes well. The building is now privately owned and well-maintained, but was previously owned and altered by Channel 4 Productions. An arson attack completely destroyed the roof during the late 20th century, but this has since been repaired. The towpath stables at the south, which are the only remnant of the previous tollhouse, have been turned into public lavatories and storage areas.

14.5 OL-05007: Old Ford Locks

Old Ford Locks have seen much alteration since their construction in the early part of the 1800s. The most violent alteration to the structure occurred during the 1940s, after a direct bomb hit destroying the lock houses, much of the lock island and chambers. Most of the lock which exists today dates to the period of rebuilding which took place after this date.

14.6 OL-05407: Pudding Mill Lock

The most significant change to the structure since its construction in the 1920s has been the demolition of the footbridge spanning the east and west tide gate. As time progressed, and the waterways were improved upon, the lock went out of use and was dismantled during the 1960s.

14.7 OL-07407: Marshgate Lane Lock

Since its construction in 1932, the lock has seen two replacement episodes; firstly during the Second World War, and secondly in more recent times, when the site around the lock was redeveloped into riverside apartments and the lock renovated. The only part of the lock site not to be replaced in recent times is the sluice gate between the City Mill and Waterworks Rivers, which is in a derelict state, full of silt and heavy vegetation.

14.8 OL-07207: Stone and Brick Riverbank Wall

The stone and brick riverbank wall is the result of two distinct building episodes. The initial episode, predating the 1850s Improvement Act, saw the laying down of the ragstone blocks,

to strengthen the natural banking of the River Lea. The later stock bricks at the top probably date to the improvements brought about by the Act. The improvements to the Old Ford area were introduced to assist and encourage transportation along the Lea Navigation and River Lea. By this point industries had moved to the area, and the printing works on Iceland Road, which occupied the land adjoining the wall, was already established. The wall represents the wharf for this works. Despite the demolition of the works and the site's recent redevelopment, the wall has remained undisturbed by later alterations schemes.

14.9 OL-03007: Carpenter's Lock

Similar to the Marshgate Lane site, Carpenter's Lock has seen two episode of replacement; firstly during the Second World War after a nearby bomb hit significantly damaged the lock gates, and secondly during the 1980s when the radial gates were mechanised. At the present time the lock is no longer functioning as a working food lock. The surrounding area is silted up, and the lock chambers are full of heavy vegetation.

14.10 OL-03507: City Mill River Footbridge

On-site observations and documentary evidence suggest that the footbridge has seen at least one phase of alterations since its construction between 1916 and 1948, and that the lattice ironwork of the bridge was replaced during the 1950s.

15 Conclusions

Industries were drawn to the Stratford area from the beginning of the 19th century by a fortuitous combination of factors that allowed them to manufacture and distribute commodities against a background of minimal regulation, low real estate and property prices and plentiful space for expansion. Industry was attracted to the area by its proximity to the London market, its location on a major road, and the availability of an extensive network of waterways for drainage, transport and power. At the same time, the growing legislative pressure to banish noxious industries from urban areas encouraged entrepreneurs to head for the open and under-populated spaces of the West Ham marshes (VCH, Essex, 1973: 77). From the 1850s onwards the increase to both industry and population in the Stratford area had a knock on effect to the infrastructure of Stratford. At this time, the waterways saw the first initial improvements that would for a time make them a vital part of Britain's industrial development.

Although the 1850s improvement works effected a marked improvement to the waterways, there followed a lack of maintenance which created watercourses that by the 1900s were hazardous to health and un-navigable for most. An article in the *Morning Leader* on the 10th December 1909 reported that Bromley Locks were remote and unknown to most Londoners: *'None but lightermen knew all the torturous and casual channels into which the Lea breaks in its old age between Bromley and Tottenham; a mesh of waterways, each with its own name, that ramify the wilderness of marsh and waste country, much of which appears to be a No-man's-land'*.

During the 1930s and the Second World War, the waterways were to see another wave of improvements. Although this initially increased the commercial traffic, their return to decrepitude was inevitable. The infrastructural improvements initiated in the beginning of the century, further improved throughout the intervening years, offered a strong rival for transport. The transport acts from the 1940s onwards ensured that the waterways were marginalised to a point where meandering recreational narrow boats used by holidaymakers and amateur boatmen soon replaced the working barges. The waterways once again became choked with weed and pollution, echoing the problems which had been so prevalent in past centuries.

By the 1980s the docks and waterways had become silent, the great buildings of the early nineteenth century had become derelict and the surrounding wharves and inland waterways unused and polluted. The backwaters returned again to a 'no-mans land', surrounded by dilapidated buildings and areas awaiting new construction, conservation or demolition. In their repeating cycle of dereliction and renewal, they are once again awaiting new life.

16 Potential of the archaeology

16.1 Original research aims

The archaeological investigation has fulfilled the original research aims through the creation of a photographic and drawn record and written description of the waterways and historic waterways-related structures.

16.2 New research aims

The information in this document is extensive, robust and goes a substantial way towards an understanding of the waterways complex, but further evidence in the form of photographs and documents is certain to exist for the construction and use of the waterways and the related structures. For example, court records (e.g. the Essex assizes) include details of cases relating to land ownership disputes along the Lea. Newspapers (e.g. The Times) include sales advertisements for properties (e.g. mills) along the Lea and its tributaries. Insurance records (e.g. those of Sun Insurance in the Guildhall library) include descriptions of properties. Further research will enhance the current understanding of the complex of waterways, the related structures and their context.

16.3 Significance of the data

The structures recorded are all associated with, and integral to, the waterways. As such they have group value and contribute to the historic evolution of the site overall, whether focused on the waterways alone or the areas along and surrounding the waterways. The group value is an important part of its significance. The impetus for cultural activity was the presence of the waterways, and the presence of the waterways drove the nature of the cultural activity: be it industrial or infrastructure-related.

The complex of waterways and related structures demonstrates the development of the area. The landscape has been adapted to meet new ideas/challenges/demands throughout, and further (and past) change to the site should be viewed in this context. The development of the site has important historic connections with its past character.

As use of the waterways declined, so did most of their associated structures: the survivals recorded here have assumed significance because of that survival. With respect to individual structures, Carpenter's Lock and Marshgate Lane Lock are the only two locks in London to possess a pair of double vertical radial gates, built more for flood defence than toll control.

Significance derives from factors that may be considered singly or combined (English Heritage 2007, 23-37):

- **Evidential value:** relates to the potential of a place to yield primary evidence about past human activity
- **Historical value:** relates to the ways in which the present can be connected through a place to past people, events and aspects of life.

- Aesthetic value: relates to way in which people derive sensory and intellectual stimulation from a place
- Communal value: relates to the meanings of a place for the people who relate to it, and those whose collective experience or memory it hold.

It is clear that these factors all apply to the features and area under discussion in this report. In particular, the site as a whole has high evidential value; presenting a well-preserved landscape that demonstrates the relationship of the waterways with the economy.

Significance is also assessed in terms of local, regional and national significance.

Self-evidently, the waterways and their integral features are of local significance: they define the locality and the nature of its development. They *are* the locality.

Regional significance is equally clear cut. The complex of waterways is not disassociated: it is integral the Lea, the Thames, the infrastructure and economy of London. The waterways, their use, the associated structures and industrial concerns were part of London when the waterways underpinned the national economy.

In these terms, the waterways must be seen as nationally significant. London was a world city, and the place of this complex of waterways was integral to the activities of London. While the Lea Navigation was a canal built to enhance the national economy, manufactories on the waterways were addressing markets across the nation and abroad (e.g. the Bow porcelain factory: situated on the edge of the Olympic park on the Bow Back River).

16.4 Salvaged fixtures, fittings and materials

There was no archaeological requirement to salvage any of the materials or fittings during the compilation of this report.

17 Publication and archiving

The site archive containing original records will be stored in accordance with the terms of the Written Schemes of Investigation (MoLAS-PCA 2007j, 2007k, 2007l, 2007m, 2007n, 2007o, 2007p & 2007q).

Information on the results of the survey will be made publicly available by means of a database in digital form, to permit inclusion of the site data in any future academic researches into the development of London.

It is also recommended that the results of this recording/analysis exercise are assimilated into a site-wide assessment of all archaeological interventions to assign contextual significance and further refine the importance of the archaeological survival, and thereafter assimilated into any publication discussing/disseminating the results.

18 Acknowledgements

The archaeological survey and this report were commissioned by the Olympic Delivery Authority, whom the project manager and author wish to thank. They are grateful especially to Nuttalls and Morrison, for facilitating access to all the areas and structures covered in this report, and to colleagues at Capita Symonds Ltd, both in and out of the field. The staff of Newham Local History Library, Tower Hamlets Local History Library, Hackney Archives Department and the London Metropolitan Archives all supplied documentary evidence.

Guy Thompson and Kari Bower conducted the archaeological research and analysis for all the built heritage structures and waterways. Recording was carried out by Helen Robertson, Clare Henshaw, Jim Heathcote, Jeremy Rogers and Kari Bower. Emma Dwyer carried out the recording and analysis of the City Mill River Footbridge. Photography was by Strephan Duckering, Edwin Baker and Maggie Cox. Rueben Lopez, Angelo Indelicato, Jennifer Simonson and Josephine Brown carried out the CAD work. The project was managed by Alex Rose-Deacon and Gary Brown.

20.1 OL-01207: The waterways overall

OASIS ID: molas1-48059

Project details	
Project name	Olympic, Paralympic and Legacy Transformations: Detailed Waterways Recording
Short description of the project	The waterways are situated with the London boroughs of Newham, Tower Hamlets and Hackney and cover a significant area of Stratford. Except for the Lea itself, the Bow Back rivers were artificially created millstreams, which in later years were also exploited for their navigability although little other physical development can be discerned during this time. Improvements took place in the 1850s and 1860s prompted by construction of the Lea Navigation and various locks at points around the Bow Back river network. By the 1870s the Rail network had started to take precedence in the area, the Great Eastern Railway (the main London to Stratford line), the North London Line and the Northern Outfall Sewer had been constructed. Their bridges became an essential component to the character of the waterways. Following the 1930 Flood Relief Act, various rivers were widened, deepened, and some were infilled or culverted. The 19th century locks were replaced and new locks were added. Post war work largely saw the waterways abandoned, infilled and culverted. mooring posts, which are situated at regular points around all the waterways could not be accurately dated through documentary research; in some cases mooring posts from earlier phases of waterway embankment have been reincorporated in later work.

20.2 OL-02007: Henniker's and Potter's Ditches

OASIS ID: molas1-47769

Project details	
Project name	Henniker's and Potter's Ditches and the Channelsea River, Stratford, E15
Short description of the project	The Channelsea River is an ancient waterway, known to have been in existence by at least the eighth century. The course and form of the river have been much altered by human intervention, including the construction of several ditches and sewers which drain into it. Among these are the medieval Potter's Ditch and the nineteenth-century Henniker's Ditch. Although ground raising in the area now means that the waterways run along the base of deep, artificial channels, some banking structures remain, including timber and stone structures. These were recorded photographically prior to redevelopment of the area under the Olympic, Paralympic and Legacy Transformations Planning Applications.

20.3 OL-02707: The Pudding Mill River

OASIS ID: molas1-47782

Project details	
Project name	Olympic, Paralympic and Legacy Transformations, PDZ3: Stone and brick riverbank wall
Short description of the project	The course of the river was recorded from its confluence with the River Lea in the N to its culverted end 340m to the SSE. Banks and structures were recorded where possible. Construction phases dating to the 1920s and 1930s were clearly evident from the presence of footbridges, a towing path bridge, cobbled surfaces and reveted banks. No earlier construction phases were recorded

20.4 OL-03007: Carpenter's Lock

OASIS ID: molas1-47808

Project details	
Project name	Waterways and Associated Built Heritage Structures: Carpenter's Lock, Stratford
Short description of the project	Carpenter's Lock is located across the River Lea channel. The lock, with the banks around it, date from a period of construction following the passing of the River Lea (Flood Relief) Act in 1930 and are constructed variously in plain concrete or in concrete over steel coffering. The locks were recorded by photo survey.

20.5 OL-03507: The City Mill River Footbridge

OASIS ID: molas1-47814

Project details	
Project name	Waterways and Associated Built Heritage Structures: City Mill River Footbridge, Stratford
Short description of the project	A footbridge running from W to E over the canalised City Mill River, just S of its junction with the River Lea, was constructed of riveted steel components. A curved central section, with lattice girder sides joined overhead and stiffened radially, was supported by straight end sections, with plate sides narrowing to the ends and stiffened vertically. Tubular steel handrails compensated for the narrowing ends. The larger flanges were stamped 'GKB PT BRITISH STEEL [?CO]NSETT', and the bridge was probably constructed between 1967 and 1980. A Level 1 record was made of the bridge on 3 and 6 September 2007, resulting in a sketch elevation, sketches of details, a short written description and photographs of the bridge and its setting.
Project dates	Start: 03-09-2007 End: 06-09-2007

20.6 OL-05007 Old Ford Locks

OASIS ID: molas1-47826

Project details

Project name	Waterways and Associated Built Heritage Structures: Old Ford Locks, Stratford		
Short description of the project	The Old Ford Locks are located on the River Lea Navigation, just north of the waterway's confluence with the River Lea. They are part of an area of historic interest that features a relatively intact fragment of a Late Victorian and Edwardian industrial estate. The locks are largely brick built and date from the mid to late 19th century. They retain fittings related to previous phases of use, such as the remains of floodgates and of gate-opening mechanisms pre-dating the current electric system. The locks were recorded by photo survey.

20.7 OL-05407: Pudding Mill Lock

OASIS ID: molas1-47829	
Project details	
Project name	Waterways and Associated Built Heritage Structures: Pudding Mill Lock, Stratford
Short description of the project	Pudding Mill Lock is located across the channel of the River Lea, north of Old Ford Lock. It dates to c.1922, and is constructed of stone, blue brick and steel. Although called a lock, the structures actually represent the remains of tide gates which separated the fully tidal section of the lower Lea Valley waterways from the semi-tidal level of the Lea Navigation. In the 1930s, the tide gates were made redundant by Carpenter's Lock to the east. The structures were recorded by photo survey.

20.9 OL-07307: Old Ford Lock Houses

OASIS ID: molas1-47849

Project details	
Project name	Waterways and Associated Built Heritage Structures: Old Ford Lock House, Old Ford
Short description of the project	The Old Ford Lock House is located on the River Lea Navigation, just north of the waterway's confluence with the River Lea. The present house is a two-storey building, with a hipped roof, it was constructed during the 1940s after Old Ford Lock was bombed in the early part of The Second World War. The house has been heavily altered in recent times by Channel 4 productions for their Big Breakfast show. The most striking alteration, being the painted exterior cement render, which imitates a red brick Flemish bond pattern with white mortar. The original windows and doorways have been removed and replaced with modern ones. The roof has retained the original hipped design, but, due to an arson attack during the late 1990s has been replaced and had skylights inserted. The small building south west of the house is currently used for both storage and public WCs. and was originally towpath stables. The exterior of which has been altered by the addition of a modern window and doorway, yellow stock bricks were used for the construction of the building. The house has been heavily altered by Channel 4 production for their Big Breakfast show and a later fire which destroyed most of the upper storeys. The house was recorded by photo survey.

21 Appendix 2: Glossary

This appendix describes the terminologies used in the report and in common use for the lock systems in use around the Bow Back River system.

In large scale river improvements weirs and locks are normally used together. A weir will increase the depth of a shallow stretch of water and the required lock will either be built in a gap in the weir, or at the downstream end of the an artificial cut which bypasses the weir and perhaps a shallow stretch of river below it. A good example in this report is Old Ford Locks.

All locks have three elements:

- A water tight **chamber** connecting the upper lower canal, which is also large enough to enclose one or more boats. The position of the chamber is fixed but the water level can vary.
- A **gate** (often a pair of ‘pointing’ half-gates) at either end of the chamber. A gate is opened to allow a boat to allow a boat to enter or leave the chamber; when closed, the gate is watertight.
- A set of **lock gears** to empty or fill the chamber as required. This is usually a simple valve or pumps (which old Ford Locks use) which allows water to drain into or out of the chamber.

Accumulator

An apparatus for collecting and storing water pressure or electricity.

Altar

A step or ledge in the wall of a dry dock, used to hold the wooden supports which steady the vessels when the dock is empty.

Apron

A platform or hard surface at the bottom of a dock entrance to intercept the fall of water and prevent the erosion of the bottom.

Balance Beam or Balance

The beam projecting from a lock gate which balances its weight, and by pushing against which the gate is opened or closed.

Bars

Horizontal beams in the structure of a lock gate.

Bollard

Wood or metal posts used for tying up boats at locks and moorings

braided channels

Contain a network of smaller channels separated by small islands called braid bars.

The number and location of the channels and braid bars may change quickly in a braided system.

The following conditions promote the formation of *braided channels*:

Erodible banks

Abundant supply of sediment

Rapid and frequent variations in stream discharge.

Breast wall

The end wall at the head of a lock, which supports the sill.

Bumping Pieces

A wooden or iron protective cladding on lock gates or the breast wall.

Caisson

A pontoon or floating gate used to close a dry dock; also a watertight chamber or other structure used, often in combination with compressed air, to keep water or soft earth out of a site during construction work; also an apparatus for lifting a vessel out of the water for repairs or inspection.

Camp shedding

A retaining wall of timber piles to protect or hold back the river bank.

Chamber

Element of a lock system is literally the water tight opening between the upper and locks allowing the water to rise and fall when required.

Chevaux de frise

A line of spikes or nails fixed along the top of a wall or railing.

Cill/ Sill

The brick or masonry or concrete bed at the bottom of lock gates

Coal-meter

One who measures or weighs coal.

Coal-whipper

One who raises coal out of a ship's hold by means of a pulley.

Cofferdam

A cofferdam (also called coffer) is an enclosure beneath the water constructed to allow water to be displaced by air for the purpose of creating a dry work environment. Commonly used construction and repair to bridges, dam and locks, the cofferdam is usually a welded steel structure that is temporary, typically dismantled after work is completed. Its components consist of sheeting, wales, and cross braces.

Counterfort

A strengthening pier or buttress in a retaining wall.

Confluence

Where two rivers meet.

Counterfort

A strengthening pier or buttress in a retaining wall.

Cross bracing (es)

Horizontal timbering which, extends across an excavation so as to support a cofferdam or sheathing.

Culvert

A channel or bricked drain used to carry a stream of water underneath or alongside another structure e.g. a road or railway.

Cut

Another word for canal, used especially for a short stretch of canal bypassing a meandering or shallow section of river.

Doubled / paired / twinned locks

Locks can be built in parallel (side by side). This can be called doubling, pairing, or twinning. There are several examples (in this case called "double locks") on the Trent and Mersey Canal north of Harecastle Tunnel. Doubling gives advantages in speed: avoiding hold-ups at busy times; or increasing the chance of a boat finding a lock set in its favour. Also, there can be water savings: the locks may be of different sizes, so that a small boat does not need to empty a large lock; or each lock may be able to act as a side pond (water-saving basin) for the other. In this latter case, the word used is usually "twinned": here indicating the possibility of saving water by synchronising the operation of the chambers so

that some water from the emptying chamber helps to fill the other. This facility has long been withdrawn on the English canals, although the disused paddle gear can sometimes be seen, as at Hillmorton on the Oxford Canal.

Other meanings: These terms can also (in different places or to different people) mean either a two-chamber staircase (Turner Wood Double Locks on the Chesterfield Canal: the same canal has a three-rise staircase called Thorpe Low Treble locks), or just a flight of two locks (as at Thornhill Double Locks on the Calder and Hebble Navigation). Also, "double lock" (less often, "twin lock") is often used by novices on the English canals to mean a wide (14 ft) lock, presumably because it is "double" the width of a narrow lock, and allows two narrow boats going in the same direction to "double up". These are properly known as broad locks.

Drawdock

An inlet in a river where boats can unload cargo or lie at low water.

Dolphin

A post, buoy or platform for mooring a vessel, sometimes situated at the entrance to a narrow harbour or dock as a guide to shipping.

Fairleads

See Snatch-heads

Effluent

Waste water left over after sewage treatment

Forebay

The breast wall and upper sill of a lock

Flood gates

A flood gate or "stop gate" is the cheaper equivalent of a flood lock. Only one set of gates exist, and so when the river is higher than the canal, the gates are closed and navigation ceases. These are quite common in the French inland waterways system. Flood gates may also be used to sub-divide long canal pounds or protect, in case of bank collapse, the surrounding area if this is lower than the water level of the canal. They are commonly found at the ends of long embankments and at aqueducts. These gates are often overlooked because they lack balance beams and are only a little higher than normal canal level.

Flood locks

A flood lock is to prevent a river from flooding a connected waterway. It is typically installed where a canal leaves a river. At normal river levels, the lock gates are left open, and the height of the canal is allowed to rise and fall with the height of the river.

However, if the river floods beyond a safe limit for the canal, then the gates are closed (and an extra lock created) until the river drops again. Since this is a true lock it is possible for boats to leave the canal for the flooded river despite the difference in water levels (though this is not likely to be wise) or (more sensibly) to allow boats caught out on the flood to gain refuge in the canal.

Note that if the canal is simply a navigation cut connecting two stretches of the same river, the flood lock will be at the upstream end of the cut (the downstream end will have a conventional lock).

Flood locks which have been used only as flood gates are often incapable of reverting to their former purpose without refurbishment. That is, where only outer gates are ever closed (probably because a waterway is not a true commercial one, and therefore there is no financial imperative for a boat to venture out onto a flooded river) inner gates soon suffer from lack of maintenance. A good example is on the Calder and Hebble Navigation, where structures referred to in the boating guides as "Flood Locks" are clearly only capable of being used for flood-prevention, not for "penning" boats to or from the river in flood.

Flood/Ground paddle

Paddles or sluices that admit water via culverts built into the ground via openings in a weir or lock gate. These relieve a canal of excess water or drain a pound for repairs, usually turning the water into a stream. Early let-offs were trap doors in the bed of the canal, pulled up by a chain. They were often difficult to work, becoming covered in mud, and a horse was sometimes needed to shift them, while there was no discharge control. Lock-type paddles which replace them were more controllable, working across a brick or stone line culvert in the canal bed or at a waste weir.

Gates

These are the watertight doors, which seal off the chamber from the upper and lower pounds. Each end of the chamber is equipped with a gate, or a pair of half gates, made of oak, elm or sometimes steel. When closed a pair meet at an angle like a chevron pointing upstream (this arrangement is often called mitre gates) and a very small difference in water-level squeezes the closed gates securely together. This reduces any leaks from between them and prevents their being opened until water levels have equalised. A lower gate is usually taller than the upper gate, because the upper gate only has to be tall enough to close off the upper pound, while the lower gate has to be able to seal off a full chamber.

Gates (steel)

Steel gates and/or balance beams are frequently used nowadays, although all-wooden versions are still fitted where appropriate.

Swinging Gates: Even very large steel-gated locks still can use essentially the same swinging gate design as small 250-year-old locks on the English canals. On English canals, steel gates usually have wooden mitre posts as this gives a better seal.

Sliding Gates: Some low-head locks use sliding steel gate.

Vertical radial gates

Gate Paddle

Paddles or sluices that admit water to a lock via the openings in a lock gate rather than via culverts built into the ground

Graving dock

A dry dock, originally a dock where ships' bottoms were cleaned and smeared with tar (a process known as graving, possibly derived from graves or greaves, the dregs of tallow).

Gridiron

A wooden framework on to which, a ship could be floated at flood tide, allowing for repairs and maintenance when the water receded.

Head Post

The vertical post farthest from the hanging point of a lock gate. Can also called a Breast or Mitre Post.

Heel Post

The corner post of a lock gate, to which the gate is fastened

Invert: an inverted arch, as at the bottom of a canal or sewer.

Hollow Quoin

The recess in which the heel post of a lock gate is fitted and turns during opening and closing.

Hydraulic paddle gear

During the 1980s British Waterways began to introduce a hydraulic system for operating paddles, especially those on bottom gates, which are the heaviest to operate. A metal cylinder about a foot in diameter was mounted on the balance beam and contained a small oil-operated hydraulic pump. A spindle protruded from the front face and was operated by a windlass in the usual way, the energy being transferred to the actual paddle by small bore pipes. The system was widely installed and on some canals it became very common. There turned out to be two serious drawbacks. It was much more expensive to install and maintain than traditional gear and went wrong more frequently, especially once the vandals learned to cut the pipes. Even worse, it had a safety defect, in that the paddle once in the raised position could not be dropped in an emergency, but had to be wound down, taking a good deal longer. These factors led to the abandonment of the policy in the late 1990s, but examples of it survive all over the system, as it is usually not removed until the gates need replacing, which happens about every twenty years.

Invert

An inverted brick, or masonry, arch as used at the bottom of a lock or tunnel.

Jigger

A loose chain used as a light warehouse crane.

Lectern

A piece of furniture with a sloping part on which a book or paper is put to be read from.

Level-luffing crane

A crane which, during luffing (the raising or lowering of the jib), maintains the load at a constant height, moving it horizontally.

Lightermen

Lightermen conveyed goods between the ships and the quayside. They took their name from this process of 'lightening' the ship. Lightermen had worked from the wharves for centuries, but secured a 'free water clause' exempting them from charges in the enclosed West India and Victoria Docks that were built during the 19th century. They were thus able to enter the docks and receive or deliver goods directly to or from vessels. This damaged the profitability of the docks and ensured that the volume of traffic handled by lightermen grew steadily throughout the 19th century.

Although Lightermen worked long hours, they enjoyed high status and considerable independence. The lightermen had an important voice in the running of the Port of London right up until the final closure of the docks in the 1980s.

Lock Distance Post

Posts set 15 or 20 yards from the head and tail of the lock. The first boat to pass the post had claim to the lock

Loophole

One of the vertical series of doors in a warehouse, through which goods are delivered by crane.

Meander

A bend in the river - usually in the middle or lower course

Mill race or raceway

Is the current or channel of a stream for conducting water to or from a water wheel or other device for utilizing its energy.

Osier bed

A place where osiers (willows) are grown for basket making

Paddle

A paddle is simply a sliding wooden (or nowadays plastic) panel which when "lifted" (slid up) out of the way allows water to either enter the chamber from the upper pound or flow out to the lower pound. A gate paddle simply covers a hole in the lower part of a gate; a more sophisticated ground paddle blocks an underground culvert. There can be up to 8 paddles (two gate paddles and two ground paddles at both upper and lower ends of the chamber) but there will often be fewer. For a long period since the 1970s it has been British Waterways policy not to provide gate paddles in replacement top gates if two ground paddles exist. The reason for this has been safety, since it is possible for an ascending boat to be swamped by the water from a carelessly lifted gate paddle. However, this makes the locks slower to operate and has been blamed in some places for causing congestion. Since the late 1990s there has been some relaxation of this policy, but it seems to be by no means universal.

Paddle Bar

The rod or shaft linking a paddle to the operating mechanism

Penstock

A sluice gate for controlling water flow, which opens by lifting upwards.

Pound

The level stretch of water between two locks (on a river, the corresponding term is commonly *reach*) The lock allows a boat to move between the pound above it (upper pound) and the pound below it (lower pound).

Powered operation

On modern canals, especially very large ones such as ship canals, the gates and paddles are too large to be hand operated, and are operated by hydraulic or electrical equipment. Even on smaller canals, some gates and paddles are electrically operated, particularly if the lock is regularly staffed by professional lock keepers. On the River Thames below Oxford all the locks are staffed and powered. Powered locks are usually still filled by gravity, though some very large locks use pumps to speed things up.

Pug mill

A machine for mixing and tempering clay.

Quoin or Coyn

The hollow quoin into which a lock gate heel post is recessed.

Rise

The change in water-level affected by the lock

River Authority

Organization set up under the Water Act of 1963 to have oversight over flood prevention, drainage, fisheries, water resources and pollution along defined Main Rivers in its area. Abolished 1974

River Board

Organization set up under the River Boards Act of 1948 to have oversight over drainage, fisheries and pollution in a particular Catchment area. Abolished 1965

Scoop wheel

A wheel driven by wind or steam for lifting water.

Scupper

An opening in the side or floor of a building to allow excess water to drain off.

Sheerlegs (also sheer legs or shearlegs):

A device for lifting heavy loads, consisting of two poles lashed together at their upper ends, from which a pulley is suspended.

Snatch-heads or fairleads

Fixtures used to alter the direction of a hauling rope or cable.

Steel Gates

Steel gates and/or balance beams are frequently used nowadays, although all-wooden versions are still fitted where appropriate.

Swinging Gates

Even very large steel-gated locks still can use essentially the same swinging gate design as small 250-year-old locks on the English canals. On English canals, steel gates usually have wooden mitre posts as this gives a better seal.

Sliding Gates: Some low-head locks use sliding steel gate

Stop locks

A "stop" lock is a (very) low-rise lock, built at the junction of two (rival) canals to prevent water from passing between them.

During the competitive years of the English waterways system, an established canal company would often refuse to allow a connection from a newer, adjacent one. This situation created the Worcester Bar in Birmingham, where goods had to be transported between boats on rival canals only feet apart.

Where a junction was built, either because the older canal company saw an advantage in a connection, or where the new company managed to insert a mandatory connection into its Act of Parliament, then the old company would seek to protect (and even enhance) its water supply. Normally, they would specify that, at the junction, the newer canal must be at a higher level than their existing canal. Even though the drop from the newer to the older canal might only be a few inches, the difference in levels still required a lock — called a stop lock, because it was to stop water flowing continuously between the newer canal and the older, lower one. The lock would be under the control of the new company, and the gates would, of course, "point" uphill - towards the newer canal. This would protect the water supply of the newer canal, but would nevertheless "donate" a lockful of water to the older company every time a boat went through. In times of excess water, of course, the lock "bywash" would continuously supply water to the lower canal.

When variable conditions meant that a higher water level in the new canal could not be guaranteed, then the older company would also build a stop lock (under its own control, with gates pointing towards its own canal) which could be closed when the new canal was low. This resulted in a sequential pair of locks, with gates pointing in opposite directions: one example was at Hall Green near Kidsgrove, where the southern terminus of the Macclesfield Canal joined the Hall Green Branch of the earlier Trent and Mersey Canal. The four gate stop lock near Kings Norton Junction, between the Stratford-upon-Avon Canal and the Worcester and Birmingham Canal was replaced in 1914 by a pair of guillotine lock gates which stopped the water flow regardless of which canal was higher. These gates have been permanently open since nationalisation.

Many stop locks were removed or converted to a single gate after nationalisation in 1948. Hall Green stop lock remains, but as a single lock: the extra lock was removed because the lowering of the T&M's summit pound (to improve Harecastle Tunnel's "air draught" — its free height above the water level) meant that the T&M would always be lower than the Macclesfield. The Hall Green Branch is now considered to be an extension of the "Macc", which now meets the T&M at Hardings Wood junction (just short of the Harecastle Tunnel north portal).

It should be noted that the "new canal must be higher" rule is not cast-iron. For instance: the very shallow lock at Atherley Junction, where the 1835 Birmingham and Liverpool canal (now part of the Shropshire Union Canal) met the older (1772) Staffordshire and Worcestershire Canal. The Nicholson guide shows that a boater coming south down the "Shroppie" locks UP before turning N or S onto the to the older S&W - so the Shroppie (the newer canal) gains a small lockful of water each time a boat passes. However, the gain is tiny since the level difference is so small that it is sometimes possible to open both gates at once.

Stop Grooves

Places provided to fit Stop Planks to dam the canal in the event of a leak or the need for repairs. These are normally found at places where the canal narrows, e.g. bridges, aqueducts and locks.

Stop Planks

A lock provided to protect the water supply of one canal company from another rather than to affect a significant change in the level of the waterway.

Strapping Post

A post, either on the lock side or the top gate, provided to hold the strap of a boat entering a lock.

Tail

Immediately below the bottom gates of a lock is the tail of the lock.

Tan Pin or Gudgeon

A pin at the foot of the heel post of a lock gate on which the gate turns.

Tidal locks

Loosely, any lock connecting tidal with non-tidal water. This includes a lock between a tidal river and the non-tidal reaches; or between a tidal river and a canal; or a sea lock. However, the term usually refers specifically to a lock whose method of operation is affected by the state of the tide.

Examples:

- 1) A canal joining a river whose levels are always lower than the canal. All that is needed is an ordinary lock, with the gates pointing up the canal. The lock is used normally so long as the tide is high enough to float boats through the lower gates. If near low tide the lock becomes unusable, then the gates can be barred (and simply become a "reverse flood gate", holding water in the canal). This arrangement also applies to some sea locks (Bude Canal).
- 2) A canal joining a river which is normally below it, but which can rise above it (at very high tides, or after heavy rain). One pair of gates can be made bidirectional, i.e. the inward-pointing gates would be supplemented by a pair pointing out to the river. When the river is higher than the canal, the normal gates would just drift open, but the additional pair of gates can be closed to protect the canal, and prevent navigation to the river. In effect, we have simply added a flood gate.
- 3) As above, but where it is safe to navigate even when the river is higher than the canal. The lock will be fully bidirectional (two pairs of oppositely pointing gates at each end) to allow boats to pass at any normal river levels. At extreme low or high tides unsuitable for navigation, the appropriate sets of gates are barred to prevent passage.

Toe

The part of the base of a dam or retaining wall on the free side, away from the retained material.

Toll

Canal tolls were based on the distance travelled, the tonnage and the type of cargo. The charges varied from canal to canal, some tolls having set maximum due to the Act of Parliament under which the canal was authorised, and some categories of goods

Towpath

Path running alongside one side of a navigable river or canal, originally used by horses drawing barges using a tow-rope. See also haling path

"Turning" a lock

This can simply mean emptying a full lock or filling an empty one (We entered the lock, and it only took us five minutes to turn it). It is used more often to refer to a lock being filled or emptied while you are not in it (The lock was turned for us by a boat coming the other way) and particularly when there is no boat in it at all (The lock was set for us, but the crew of the boat coming the other way turned it before we got there).

Tumbling Bay

An overfall or weir in a canal

Water Authority

Organization set up under the Water Act of 1973 to have comprehensive management of the entire water cycle, including flood prevention, drainage, fisheries, water resources, pollution, water supply and sewage. Privatized 1989

Watercress Bed

A badly leaking boat

Wales or whales

Horizontal supports (usually of timber, sometimes of iron) used to bind together piles driven in a row.

Winding gear / paddle gear

The mechanism which allows paddles to be lifted (opened) or lowered (closed). Typically, a square-section stub emerges from the housing of the winding gear. This is the axle of a sprocket ("pinion") which engages with a toothed bar ("rack") protruding from the top of the paddle. A member of the boat's shore crew engages the square socket of their windlass (see below) onto the end of the axle and turns the windlass perhaps a dozen times. This rotates the pinion and lifts the paddle. A pawl engages with the rack to prevent the paddle from dropping inadvertently while being raised, and to keep it raised when the windlass is removed, so that the operator can attend to other paddles (it is considered discourteous and wasteful of water to leave a paddle open after a boat has left the lock). To lower a paddle the pawl must be disengaged and the paddle wound down with the windlass. Dropping paddles by knocking the pawl off can cause damage to the mechanism – the paddle gear is

typically made of cast iron and can shatter or crack when dropped from a height. In areas where water-wastage due to vandalism is a problem, for example the Birmingham Canal Navigations), paddle mechanisms are commonly fitted with vandal-proof locks (nowadays called "water conservation devices", which the authorities believe sounds nicer) which require the boater to employ a key called a "handcuff key" before the paddle can be lifted.

Water Act 1945

This brought together previous water legislation and introduced a waterworks code. It encouraged amalgamations of water companies and boards. A government survey 30 years earlier identified 2,160 water undertakings including 786 local authorities.

By 1963 the numbers had reduced to:

100 water boards (each comprising two or more local authorities), 50 local authorities and 29 privately owned statutory water companies.

The privately owned companies provided approximately one quarter of the water supply in England and Wales.

The River Boards Act of 1948

The boards were established by the River Boards Act 1948 and replaced the Catchment Boards that had been created in 1931. They were given powers to regulate fisheries and took over the duties of flood prevention from local authorities. England and Wales (except the Thames and Lee catchment areas, the County of London and some adjoining areas) was divided into River Board Areas, each with a board partly nominated by county councils and county borough corporations, and partly appointed by the government.

The Act allowed that "orders defining river board areas and establishing river boards may be made at different times for different areas". It was not until 1955 that all the boards had been established.

Water Resources Act 1963 (c.38)

An Act to provide for the establishment of river authorities and a Water Resources Board, to confer on them, and on the Minister of Housing and Local Government, new functions in relation to water resources in England and Wales, and to provide for the transfer to river authorities of functions previously exercisable by river boards and other bodies; to make further provision for controlling the abstraction and impounding of water, for imposing charges in respect of licences to abstract or impound water, and for securing the protection and proper use of inland waters and water in underground strata; to enable corresponding provision to be made in relation to the Thames and Lee catchment areas and certain other areas in or adjacent to London; and for purposes connected with the matters.

[31st July 1963]

Water Act 1973

The Act created the ten water authorities that were later privatised. They took over from the local authorities and water boards and their role was "to plan and control all users of water in each river catchment area". They had responsibilities for:

water conservation.

controlling pollution of inland and tidal waters.

land drainage and flood control.

fisheries.

supply of water and sewerage services.

The Chairman was appointed by the Secretary of State and the majority of the members were from local authorities. The ten water authorities were subject to government targets and financial control like nationalised industries. Customers' bills continued to be calculated on the basis of rateable values.

Water Act 1983

This changed the organisational structure of the water authorities. Local authorities lost some rights of representation and meetings were closed to the press and public. To compensate for the reduction in public involvement consumer consultative committees (CCC) were set up in each authority with limited powers. The water authorities appointed CCC members from organisations invited to put names forward. A representative of the water authority also sat on each committee.
