# 1 SUMMARY OF RESULTS

A detailed magnetometry survey was conducted over approximately 10.5 hectares of arable land. A curvilinear anomaly and several probable pits have been detected, and appear in line with known cropmarks recorded in the area. It is likely that these features represent former cut features of archaeological origin Evidence of ridge and furrow cultivation, modern ploughing and a trackway on the site indicate the area has an agricultural past. Magnetic disturbance from nearby fences, and magnetic spikes are the only other anomalies to have been detected.

# 2 INTRODUCTION

## 2.1 Background synopsis

Stratascan were commissioned to undertake a geophysical survey of an area outlined for residential development. This survey forms part of an archaeological investigation being undertaken by Worcestershire County Council.

## 2.2 Site Details

NGR / Postcode	SP 073 513 / WR11 8XD
Location	The site is located to the north of Salford Priors, Warwickshire. School Road forms the north-eastern boundary of the site, with agricultural land to the south and west, and a residential area to the south-east.
HER/SMR	Warwickshire
District	Stratford-on-Avon
Parish	Salford Priors CP
Topography	The site lies on a very gentle north-west to south-east slope
Current Land Use	Arable
Weather Conditions	Overcast
Soils	The overlying soils are known as Arrow (543) which are typical gleyic brown earths. These consist of deep, permeable, coarse loamy soils (Soil Survey of England and Wales, Sheet 3 Midland and Western England).
Geology	The underlying geology comprises mudstone of Mercia Mudstone group. The drift geology is sand and gravel of Wasperton Sand and Gravel Member (British Geological Survey website).

Archaeology	Extract from "School Road, Salford Priors, Warwickshire – Archaeological Desk-Based Assessment" (Archaeology Warwickshire, 2014): Aerial photographs have identified a series of cropmarks across the Proposed Development Area (PDA) (transcribed on Fig 1). On typological grounds the identifiable features could date to between the Early Neolithic to Romano-British period (Historic Environment Record MWA 6291) and it is possible that more than one of these periods is represented. The archaeological remains include a curvilinear boundary with pit groups which appear to respect it (MWA 12382), linear features which could represent more than one phase of activity, several ring ditches, which could be dwellings or round barrows and at least two enclosures. Examination of the aerial photographs (CUCAP COP18 & CGL50) suggests that the number of pits could be much greater than shown on the transcript. The cropmarks continue to the north and may, therefore, be associated with the double ditched enclosure (MWA 1497). There are also hints that medieval ridge and furrow ploughing may have been present across the PDA.
Survey Methods	Detailed magnetic survey (gradiometry)
Study Area	c. 10.5 hectares

### 2.3 Aims and objectives

To locate and characterise any anomalies of possible archaeological interest within the study area.

# 3 METHODS, PROCESSING & PRESENTATION

### 3.1 Standards & Guidance

This report and all fieldwork have been conducted in accordance with the latest guidance documents issued by Historic England (2008) and the Chartered Institute for Archaeologists (2002 & 2014).

Stratascan Ltd are a Registered Organisation with the CIfA and are committed to upholding its policies and standards.

### 3.2 Survey methods

Due to the cropmarks identified across the eastern part of the survey area, detailed magnetic survey was used as an efficient and effective method of locating archaeological anomalies.

More information regarding this technique is included in Appendix A.

#### 3.3 Processing

The following schedule shows the basic processing carried out on the data used in this report:

- 1. De-stripe
- 2. De-stagger

## 3.4 Presentation of results and interpretation

The presentation of the data for each site involves a plot of the minimally processed data as a greyscale plot and a colour plot showing extreme magnetic values. Magnetic anomalies have been identified and plotted onto the 'Interpretation of Anomalies' drawing.

When interpreting the results several factors are taken into consideration, including the nature of archaeological features being investigated and the local conditions at the site (geology, pedology, topography etc.). Anomalies are categorised by their potential origin. Where responses can be related to very specific known features documented in other sources, this is done (for example: Abbey Wall, Roman Road). For the generic categories levels of confidence are indicated, for example: probable, or possible archaeology. The former is used for a confident interpretation, based on anomaly definition and/or other corroborative data such as cropmarks. Poor anomaly definition, a lack of clear patterns to the responses and an absence of other supporting data reduces confidence, hence the classification "possible".

## 4 **RESULTS**

The detailed magnetic gradiometer survey conducted at Salford Priors has identified a number of anomalies that have been characterised as being of *probable* archaeological origin. The following **[1-6]** refers to numerical labels on the interpretation plots.

## 4.1 **Probable Archaeology**

A positive linear anomaly [1] and area of enhanced response [3] in the eastern area are indicative of a former cut feature, such as a ditch, while further discrete positive anomalies [2] are indicative of smaller cut features, such as backfilled pits. These anomalies appear to follow a similar line to the cropmarks recorded in the area, and as such have been classified as probable archaeology.

## 4.2 Possible Archaeology

No possible archaeology has been identified within the survey area.

## 4.3 Medieval/Post-Medieval Agriculture

Relatively widely spaced, parallel linear anomalies **[4]** are related to ridge and furrow cultivation. Magnetically weak, closely spaced, parallel linear anomalies **[5]** across the western field are a result of modern agricultural activity, such as ploughing. A weakly enhanced linear anomaly **[6]** is related to a former trackway visible on available OS mapping from 1971 to 1978.

## 4.4 **Other Anomalies**

Areas of magnetic disturbance around field edges area results of nearby ferrous objects, such as fencing. The effects of this disturbance has the potential to mask weaker archaeological anomalies, but have not affected a significant proportion of the area on this site. Smaller 'magnetic spikes' are likely to be modern rubbish or a spread of magnetic debris in the top soil.

## 5 DATA APPRAISAL & CONFIDENCE ASSESSMENT

Both underlying mudstone geologies and superficial deposits of sand and gravel can provide variable results for magnetic survey. In this instance, the bedrock and drift geologies appear to be conducive to magnetic survey given that archaeological anomalies have been detected. Though it may be possible that the effects of modern ploughing in the north-west area could mask weak archaeological anomalies, however any stronger responses are likely to have been detected.

# 6 **CONCLUSION**

The survey at Salford Priors has identified a number of anomalies of probable archaeological origin. A curvilinear anomaly and several pits have been detected, and appear in line with known cropmarks recorded in the area. It is likely that these features represent former cut features of archaeological origin. Evidence of ridge and furrow cultivation, modern ploughing and a trackway on the site indicate the area has been used for agricultural purposes since the medieval period. The remaining features are modern and include magnetic disturbance from nearby fences, and magnetic spikes which are likely to be modern rubbish.

# **Appendix A - Technical Information: Magnetometer Survey Method**

#### **Grid Positioning**

For hand held gradiometers the location of the survey grids has been plotted together with the referencing information. Grids were set out using a Trimble R8 Real Time Kinematic (RTK) VRS Now GNSS GPS system.

An RTK GPS (Real-time Kinematic Global Positioning System) can locate a point on the ground to a far greater accuracy than a standard GPS unit. A standard GPS suffers from errors created by satellite orbit errors, clock errors and atmospheric interference, resulting in an accuracy of 5m-10m. An RTK system uses a single base station receiver and a number of mobile units. The base station re-broadcasts the phase of the carrier it measured, and the mobile units compare their own phase measurements with those they received from the base station. This results in an accuracy of around 0.01m.

Technique	Instrument	Traverse Interval	Sample Interval
Magnetometer	Bartington Grad 601-2	1m	0.25m

#### Instrumentation: Bartington Grad601-2

Bartington instruments operate in a gradiometer configuration which comprises fluxgate sensors mounted vertically, set 1.0m apart. The fluxgate gradiometer suppresses any diurnal or regional effects. The instruments are carried, or cart mounted, with the bottom sensor approximately 0.1-0.3m from the ground surface. At each survey station, the difference in the magnetic field between the two fluxgates is measured in nanoTesla (nT). The sensitivity of the instrument can be adjusted; for most archaeological surveys the most sensitive range (0.1nT) is used. Generally, features up to 1m deep may be detected by this method, though strongly magnetic objects may be visible at greater depths. The Bartington instrument can collect two lines of data per traverse with gradiometer units mounted laterally with a separation of 1.0m.

The readings are logged consecutively into the data logger which in turn is daily down- loaded into a portable computer whilst on site. At the end of each site survey, data is transferred to the office for processing and presentation.

#### **Data Processing**

Zero MeanThis process sets the background mean of each traverse within each grid to zero. The<br/>operation removes striping effects and edge discontinuities over the whole of the data set.Step CorrectionWhen gradiometer data are collected in 'zig-zag' fashion, stepping errors can sometimes<br/>arise. These occur because of a slight difference in the speed of walking on the forward<br/>and reverse traverses. The result is a staggered effect in the data, which is particularly<br/>noticeable on linear anomalies. This process corrects these errors.

#### Display

Greyscale/ This format divides a given range of readings into a set number of classes. Each class is Colourscale Plot represented by a specific shade of grey, the intensity increasing with value. All values above the given range are allocated the same shade (maximum intensity); similarly all values below the given range are represented by the minimum intensity shade. Similar plots can be produced in colour, either using a wide range of colours or by selecting two or three colours to represent positive and negative values. The assigned range (plotting levels) can be adjusted to emphasise different anomalies in the data-set.

#### Interpretation Categories

In certain circumstances (usually when there is corroborative evidence from desk based or excavation data) very specific interpretations can be assigned to magnetic anomalies (for example, *Roman Road, Wall,* etc.) and where appropriate, such interpretations will be applied. The list below outlines the generic categories commonly used in the interpretation of the results.

 Archaeology/Probable
 This term is used when the form, nature and pattern of the response are clearly or very probably archaeological and /or if corroborative evidence is available. These anomalies, whilst considered anthropogenic, could be of any age.

 Passible
 Archaeology

 Passible
 Archaeology

 Image: Description
 These anomalies or form

- Possible Archaeology These anomalies exhibit either weak signal strength and / or poor definition, or form incomplete archaeological patterns, thereby reducing the level of confidence in the interpretation. Although the archaeological interpretation is favoured, they may be the result of variable soil depth, plough damage or even aliasing as a result of data collection orientation.
- Industrial /Strong magnetic anomalies that, due to their shape and form or the context in which theyBurnt-Firedare found, suggest the presence of kilns, ovens, corn dryers, metal-working areas orhearths. It should be noted that in many instances modern ferrous material can producesimilar magnetic anomalies.

Former Field Boundary Anomalies that correspond to former boundaries indicated on historic mapping, or which (probable & possible) are clearly a continuation of existing land divisions. Possible denotes less confidence where the anomaly may not be shown on historic mapping but nevertheless the anomaly displays all the characteristics of a field boundary.

- *Ridge & Furrow* Parallel linear anomalies whose broad spacing suggests ridge and furrow cultivation. In some cases the response may be the result of more recent agricultural activity.
- AgricultureParallel linear anomalies or trends with a narrower spacing, sometimes aligned with<br/>existing boundaries, indicating more recent cultivation regimes.
- Land Drain Weakly magnetic linear anomalies, quite often appearing in series forming parallel and herringbone patterns. Smaller drains will often lead and empty into larger diameter pipes and which in turn usually lead to local streams and ponds. These are indicative of clay fired land drains.
- *Natural* These responses form clear patterns in geographical zones where natural variations are known to produce significant magnetic distortions.

Magnetic Disturbance Broad zones of strong dipolar anomalies, commonly found in places where modern ferrous or fired materials (e.g. brick rubble) are present. They are presumed to be modern.

- Service Magnetically strong anomalies usually forming linear features indicative of ferrous pipes/cables. Sometimes other materials (e.g. pvc) cause weaker magnetic responses and can be identified from their uniform linearity crossing large expanses.
- FerrousThis type of response is associated with ferrous material and may result from small items<br/>in the topsoil, larger buried objects such as pipes, or above ground features such as fence<br/>lines or pylons. Ferrous responses are usually regarded as modern. Individual burnt<br/>stones, fired bricks or igneous rocks can produce responses similar to ferrous material.
- Uncertain OriginAnomalies which stand out from the background magnetic variation, yet whose form and<br/>lack of patterning gives little clue as to their origin. Often the characteristics and<br/>distribution of the responses straddle the categories of Possible Archaeology and Possible<br/>Natural or (in the case of linear responses) Possible Archaeology and Possible Agriculture;<br/>occasionally they are simply of an unusual form.

Where appropriate some anomalies will be further classified according to their form (positive or negative) and relative strength and coherence (trend: weak and poorly defined).

# **Appendix B - Technical Information: Magnetic Theory**

Detailed magnetic survey can be used to effectively define areas of past human activity by mapping spatial variation and contrast in the magnetic properties of soil, subsoil and bedrock. Although the changes in the magnetic field resulting from differing features in the soil are usually weak, changes as small as 0.2 nanoTeslas (nT) in an overall field strength of 48,000nT, can be accurately detected.

Weakly magnetic iron minerals are always present within the soil and areas of enhancement relate to increases in *magnetic susceptibility* and permanently magnetised *thermoremanent* material.

Magnetic susceptibility relates to the induced magnetism of a material when in the presence of a magnetic field. This magnetism can be considered as effectively permanent as it exists within the Earth's magnetic field. Magnetic susceptibility can become enhanced due to burning and complex biological or fermentation processes.

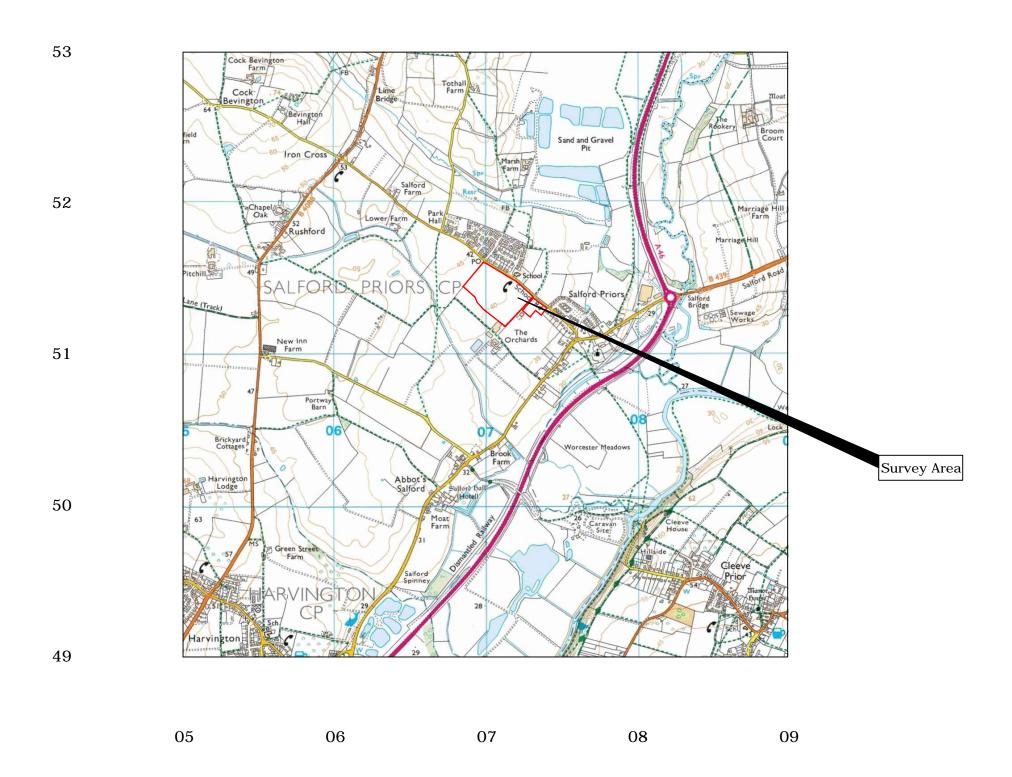

Thermoremanence is a permanent magnetism acquired by iron minerals that, after heating to a specific temperature known as the Curie Point, are effectively demagnetised followed by re-magnetisation by the Earth's magnetic field on cooling. Thermoremanent archaeological features can include hearths and kilns and material such as brick and tile may be magnetised through the same process.

Silting and deliberate infilling of ditches and pits with magnetically enhanced soil creates a relative contrast against the much lower levels of magnetism within the subsoil into which the feature is cut. Systematic mapping of magnetic anomalies will produce linear and discrete areas of enhancement allowing assessment and characterisation of subsurface features. Material such as subsoil and non-magnetic bedrock used to create former earthworks and walls may be mapped as areas of lower enhancement compared to surrounding soils.

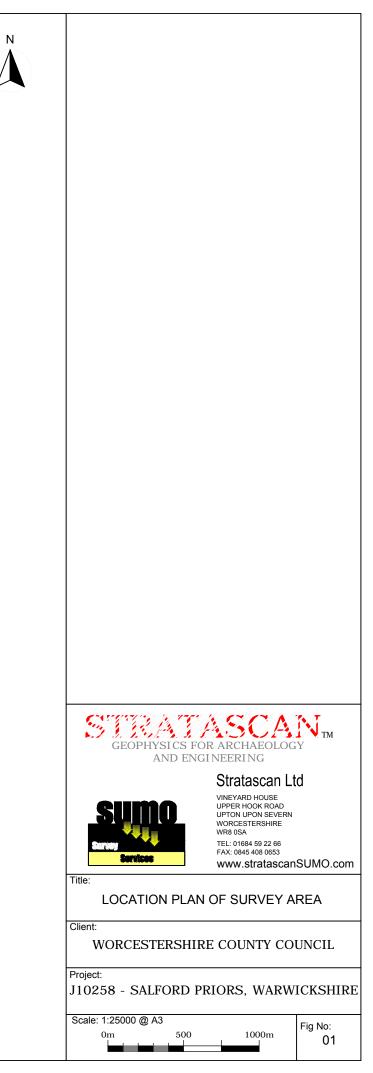

Magnetic survey is carried out using a fluxgate gradiometer which is a passive instrument consisting of two sensors mounted vertically 1m apart. The instrument is carried about 30cm above the ground surface and the top sensor measures the Earth's magnetic field whilst the lower sensor measures the same field but is also more affected by any localised buried field. The difference between the two sensors will relate to the strength of a magnetic field created by a buried feature, if no field is present the difference will be close to zero as the magnetic field measured by both sensors will be the same.

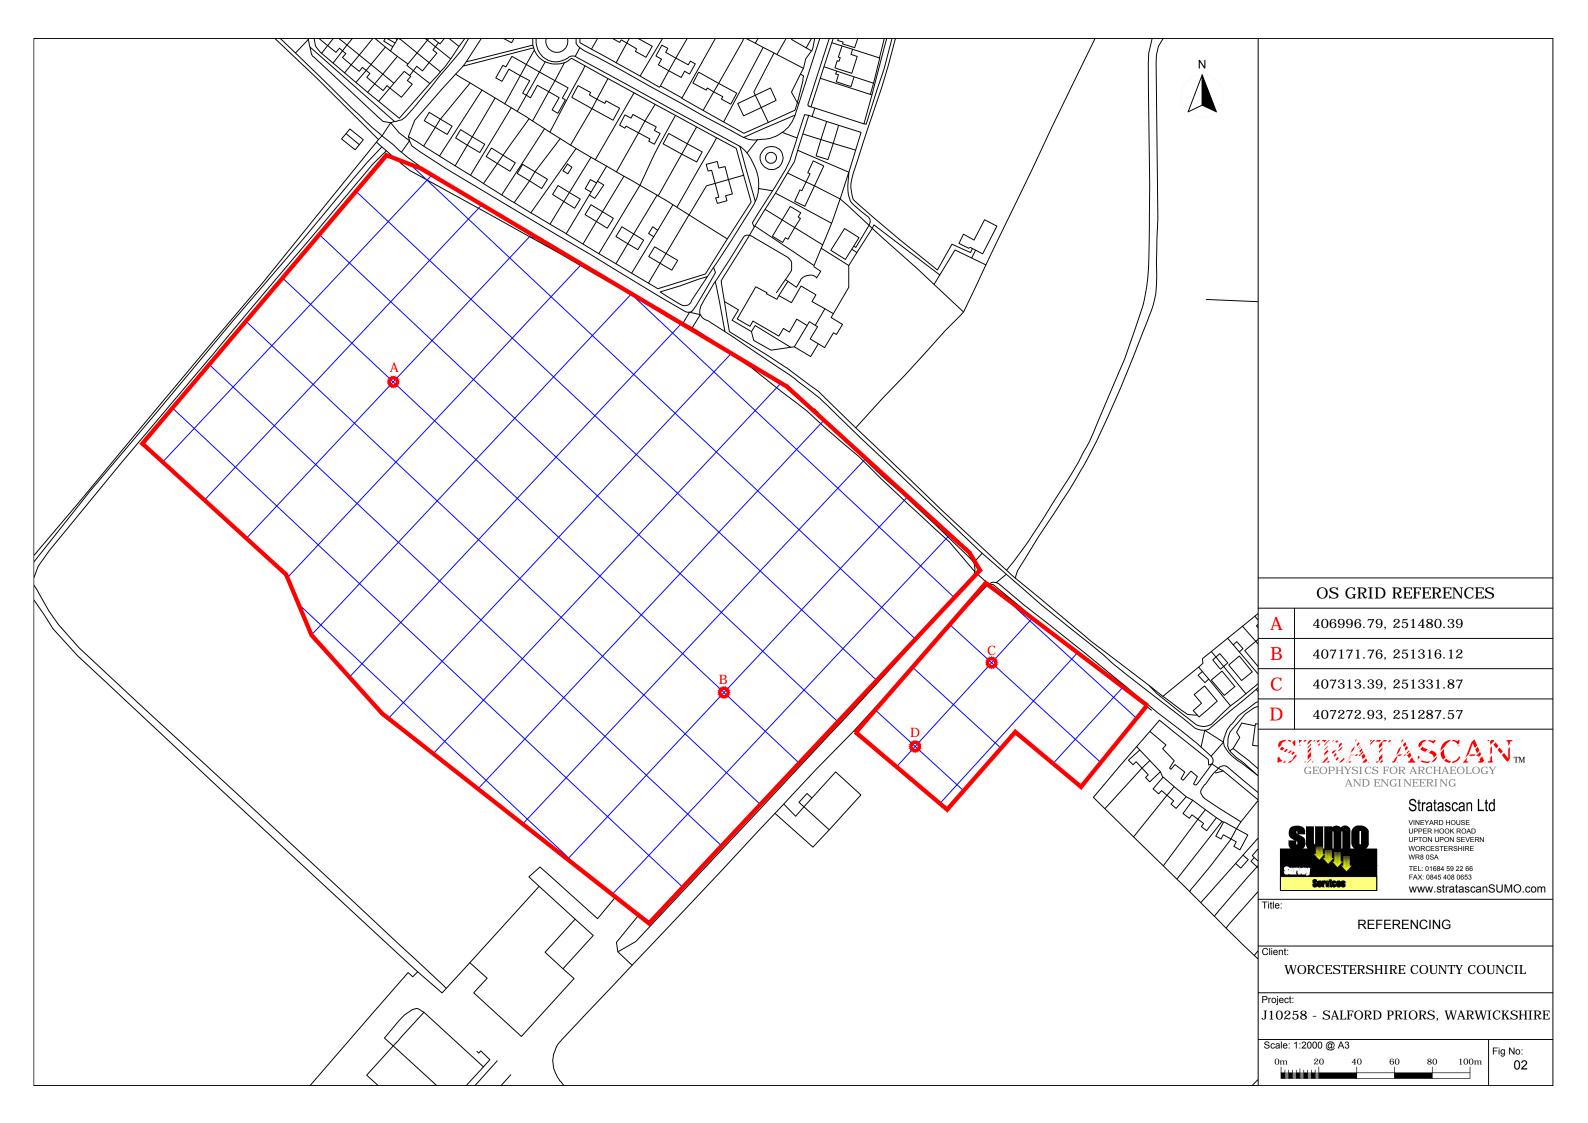

Factors affecting the magnetic survey may include soil type, local geology, previous human activity, disturbance from modern services etc.
