Appendix 1: Methodology

1. Mapping of features

Mapping allowed for the plotting of the following features (attributes):

- Fishponds
- Marsh/reed swamp
- Meander loop (pronounced stream/river meander)
- Meander movement (where a meander has moved position since the First Edition Ordnance Survey mapping, leaving behind relict stream channel deposits OR where a parish boundary has followed a watercourse, and a meander has moved away from the boundary, potentially leaving behind relict marsh deposits post dating the parish boundary)
- Moat
- Osier bed
- Palaeochannel (includes cut off meanders)
- Pond
- Other (includes for example water meadows, mill leats, occasional mill ponds)

The features were identified on a separate layer using the 1st Edition OS map as a basemap. The GIS layers used for verification during the process were as follows:

- Worcestershire HER mapping (linears and polygons)
- Historical mapping 2nd Edition (1891 - 1912)
- Historical mapping 7th Edition (1954 – 1963)
- Current OS 1:10,000 colour
- LiDAR (high resolutions JPGs) –Environment Agency (EA) Hi-Res JPEGs countywide, for Grow With Wyre (GWW) and Severn Geoarchaeology project areas, hillshaded LiDAR models were used
- Aerial photographs (APs from 1999 and 2005, or Google Earth)
- Wetlands West, Longdon Marsh area

Polygons were traced around each feature type and relevant information on each feature added in an attribute table.

Following work in the Forest of Dean (Pearson *et al* 2011) and the Wyre Forest (Pearson and Daffern 2012) adjustments were made to the basis of mapping of palaeochannels, which can sometimes prove to be at least seasonally active despite not showing on modern maps. These were only mapped where they were not visible on aerial photographs, and on LiDAR showed as a definite channel, at least 2m wide.

2. Assessment of features

During the mapping phase features were scored according to their potential for organic deposits to survive and for their accessibility. This is a basic level of scoring intended to be used as a first stage of assessment of the mapped features (and is irrespective of the date of the feature). The table below shows the questions that were applied to each feature to facilitate the scoring of potential and the source referred to. The scores were weighted to take account of how important these aspects are in assessing the potential.

The size of the feature is particularly important as the larger the feature the greater the potential for organic deposits to survive. Larger volumes of organic material are less prone to

wetting and drying and consequently decay. The potential for recovering a sequence which represents a long time span and several phases of environmental change is also greater. For this work only surface area can be recorded as depth cannot be ascertained and therefore volume (the ideal measurement) is unknown.

	Questions	LOW		HIGH
A	To what level is the feature accessible/covered? (Assessed from modern map)	Fully Covered 1	Semi/Partially Covered 3	Open 5
B	What scale/size is the feature? (Info taken from attribute table)	Small (<500m ²) 1	Medium (501-1999m ²) 3	Large (2000> m ²) 6
C	Has there been any change in the extent of waterlogging? (1 st Ed OS, modern maps and AP's compared)	Major Change (No longer mapped) 1	Minor Change (A decrease but still there) 2	No Change or a 'Positive' Change 3
	Is there any associated information with or related to the feature? (Take from HER layer)	No Leave blank		Yes Add comment

The extent to which there have been changes in waterlogging of the features has also been used to assess the potential for organic deposits to survive. This was estimated by comparing the extent of waterlogging indicated on both 1st Edition OS and the modern OS maps (also by referring to any aerial photographs available). Any major drying out may have caused decay of organic deposits.

The accessibility of the mapped features was determined by categorising these as 'open' 'semi-open' or 'covered' according to the modern OS map and any aerial photographs available. The extent to which cover will have damaged the deposits and the likelihood of this cover being removed may vary with the type of cover (trees, buildings or hard surfaces for example). For this reason the type of cover was noted in the GIS attributes table as an aid to assessing potential. The appearance of tree coverage has been shown through previous work (Pearson 2010, Pearson *et al* 2011 and Pearson and Daffern 2012) to appear more dense on aerial photographs than when viewed on the ground. As a result of recommendations made through work on the Grow With Wyre project (Pearson and Daffern 2012), tree cover was only reflected in the 'coverage' score if tree cover was dense, and where tree cover was dense and extensive, the coverage was scored as 'partial' or '3'.

In addition, where information on the history or archaeology of a feature was available on the HER it was added to the attribute table and was flagged on the GIS map. This information was not used in scoring potential as, for instance, availability of documentary evidence on a medieval moat may improve the potential of this feature for projects focussing on medieval landscape but not for those focussing on prehistoric landscape: potential needs to be considered in a more general form.

The overall potential of the features was categorised as high, medium and low based on the scores detailed above as follows high (green) = 10–14, medium = 8–9 and low = up to 7.
